PREFACE

C is not a large language. Measured by the weight of its reference manual, C could even be classified as small. The small size reflects a lack of confining rules rather than a lack of power. Users of C learn early to appreciate the elegance of expression afforded by its clear design.

Such elegance might seem needlessly arcane for new C programmers. The lack of restrictiv means that C programs can be and are written with full-bodied expressions that may appear printing errors to the novice. The cohesiveness of C often admits clear, but terse, ways express common programming tasks.

The process of learning C, as for any programming language, may be modeled by three steps (no doubt repeated many times over). Step one is to understand the language syntax, at least to the point where the translator no longer complains of meaningless constructions. Step two is to know what meaning the translator will ascribe to properly formed constructions. And step three is to develop a programming style fitting for the language; it is the art of writing clear, concise, and correct programs.

The puzzles in this book are designed to help the reader through the second step. They challenge the reader’s mastery of the basic rules of C and lead the reader into seldom reached corners, beyond reasonable limits, and past a few open pits. (Yes, C, as all real languages, has its share of obscurities that are learned by experience.)

The puzzles should not be read as samples of good coding; indeed, some of the code is atrocious. But this is to be expected. Often the same qualities that make a program poor make a puzzle interesting:

- ambiguity of expression, requiring a rule book to interpret;
- complexity of structure, data and program structure not easily kept in one’s head;
- obscurity of usage, using concepts in nonstandard ways.

C is still an evolving language. Depending upon the vintage of your local compiler, some features explored here may not be implemented and some of the implemented features may not be explored here. Fortunately, the evolution of C has proceeded uniformly, so it is very unlikely that your compiler will have a feature implemented in a different way than described here.

HOW TO USE THIS BOOK

The C Puzzle Book is a workbook intended to be used with a C language textbook such as The Programming Language by Brian Kernighan and Dennis Ritchie (Prentice-Hall, 1978). The book is divided into sections with one major topic per section. Each section comprises programs that explore different aspects of the section topic. The programs are sprinkled with print statements. The primary task is to discover what each program prints. All of th
programs are independent of one another, though the later puzzles assume that you understand 
the properties of C illustrated in earlier puzzles.

The output for each program is given on the page following the text of the program. Each of 
the programs was run from the text under the UNIX† Operating System on Digital Equipment 
Corporation PDP 11/70 and VAX 11/780 computers. For the few cases where the output is 
different on the two machines, output is given from both.

The larger portion of the book is devoted to step-by-step derivations of the puzzle solutions. 
Many of the derivations are accompanied by tips and caveats for programming in C.

A typical scenario for using the puzzles might go like this:

- Read about a topic in the language textbook.
- For each program in the puzzle book section on the topic
  - Work the puzzles of the program.
  - Compare your answers to the program output.
  - Read the solution derivations.

ACKNOWLEDGEMENTS

The first C puzzles were developed for an introductory C programming course that I taught at 
Bell Laboratories. The encouraging response from students led me to hone the puzzles and 
embellish the solutions. A number of my friends and colleagues have given valuable 
comments and corrections to various drafts of this book. They are Al Boysen, Jr., Jeannette 
Feuer, Brian Kernighan, John Linderman, David Nowitz, Elaine Piskorik, Bill Roome, Keith 
Vollherbst, and Charles Wetherell. Finally, I am grateful for the fruitful environment and 
generous support provided me by Bell Laboratories.

Alan Feuer

PUZZLES
Operators

1. Basic Arithmetic Operators
2. Assignment Operators
3. Logic and Increment Operators
4. Bitwise Operators
5. Relational and Conditional Operators
6. Operator Precedence and Evaluation

C programs are built from statements, statements from expressions, and expressions from operators and operands. C is unusually rich in operators; see the operator summary of Appendix 2 if you need convincing. Because of this richness, the rules that determine how operators apply to operands play a central role in the understanding of expressions. The rules, known as precedence and associativity, are summarized in the precedence table of Appendix 1. Use the table to solve the problems in this section.
Operators 1: Basic Arithmetic Operators

What does the following program print?

```c
main()
{
    int x;
    x = - 3 + 4 * 5 - 6; printf("%d\n",x); (Operators 1.1)
    x = 3 + 4 % 5 - 6; printf("%d\n",x); (Operators 1.2)
    x = - 3 * 4 % 6 / 5; printf("%d\n",x); (Operators 1.3)
    x = ( 7 + 6 ) % 5 / 2; printf("%d\n",x); (Operators 1.4)
}
```
Operators 1: Basic Arithmetic Operators

Output:

11 (Operators 1.1)
1 (Operators 1.2)
0 (Operators 1.3)
1 (Operators 1.4)

Derivations begin on page 77.

Operators 2: Assignment Operators

What does the following program print?

```c
#define PRINTX printf("%d\n",x)

main()
{
    int x=2, y, z;

    x *= 3 + 2; PRINTX; (Operators 2.1)
    x *= y = z = 4; PRINTX; (Operators 2.2)
    x = y == z; PRINTX; (Operators 2.3)
    x == ( y = z ); PRINTX; (Operators 2.4)
}
```
Operators 2: Assignment Operators

OUTPUT:

10 (Operators 2.1)
40 (Operators 2.2)
1 (Operators 2.3)
1 (Operators 2.4)

Solutions begin on page 80.

Operators 3: Logic and Increment Operators

What does the following program print?

```c
#define PRINT(int) printf("%d\n", int)

main()
{
    int x, y, z;

    x = 2; y = 1; z = 0;
    x = x && y || z; PRINT(x);
    PRINT( x || ! y && z );

    x = y = 1;
    z = x ++ - 1; PRINT(x); PRINT(z);
    z += x ++ + ++ y; PRINT(x); PRINT(z);
    z = x / ++ x; PRINT(z);
}
```

(Operators 3.1)
(Operators 3.2)
(Operators 3.3)
(Operators 3.4)
(Operators 3.5)
Operators 3: Logic and Increment Operators

**OUTPUT:**

1. (Operators 3.1)
2. (Operators 3.2)
3. (Operators 3.3)
4. (Operators 3.4)
5. (Operators 3.5)

Solutions begin on page 83.

---

Operators 4: Bitwise Operators

What does the following program print?

```c
#define PRINT(int) printf("int = %d\n",int)

main()
{
    int x, y, z;
    x = 03; y = 02; z = 01;
    PRINT(x | y & z);   (Operators 4.1)
    PRINT(x | y - z);   (Operators 4.2)
    PRINT(x ^ y & -z);  (Operators 4.3)
    PRINT(x & y && z);  (Operators 4.4)

    x = 1; y = -1;
    PRINT( !x | x );    (Operators 4.5)
    PRINT( ~x | x );    (Operators 4.6)
    PRINT( x ^ x );    (Operators 4.7)
    x <<= 3; PRINT(x);  (Operators 4.8)
    y <<= 3; PRINT(y);  (Operators 4.9)
    y >>= 3; PRINT(y);  (Operators 4.10)
}
```
OUTPUT:

\[ x \mid y \& z = 3 \quad (\text{Operators 4.1}) \]
\[ x \mid y \& -z = 3 \quad (\text{Operators 4.2}) \]
\[ x \land y \& -z = 1 \quad (\text{Operators 4.3}) \]
\[ x \& y \&\& z = 1 \quad (\text{Operators 4.4}) \]
\[ x \mid x = 1 \quad (\text{Operators 4.5}) \]
\[ -x \mid x = -1 \quad (\text{Operators 4.6}) \]
\[ x \land x = 0 \quad (\text{Operators 4.7}) \]
\[ x = 8 \quad (\text{Operators 4.8}) \]
\[ y = -8 \quad (\text{Operators 4.9}) \]
\[ y = ? \quad (\text{Operators 4.10}) \]

Derivations begin on page 86.

What does the following program print?

```c
#define PRINT(int) printf("int = %d\n",int)

main()
{
    int x=1, y=1, z=1;
    x += y += z;
    PRINT( x < y ? y : x );
    PRINT( x < y ? x ++ : y ++ );
    PRINT(x); PRINT(y);
    PRINT( z += x < y ? x ++ : y ++ );
    PRINT(y); PRINT(z);
    x=3; y=z=4;
    PRINT( (z >= y >= x) ? 1 : 0);
    PRINT( z >= y \&\& y >= x );
}
```

(Operators 5.1)
(Operators 5.2)
(Operators 5.3)
(Operators 5.4)
(Operators 5.5)
Operators 5: Relational and Conditional Operators

OUTPUT:

\[ x < y \ ? \ y \ : \ x = 3 \]  
\[ x < y \ ? \ x ++ : \ y ++ = 2 \]  
\[ x = 3 \]  
\[ y = 3 \]  
\[ z += x < y \ ? \ x ++ : \ y ++ = 4 \]  
\[ y = 4 \]  
\[ z = 4 \]  
\[ (z >= y >= x) ? 1 : 0 = 0 \]  
\[ z >= y && y >= x = 1 \]  

Derivations begin on page 91.

Operators 6: Operator Precedence and Evaluation

What does the following program print?

```c
#define PRINT3(x,y,z) printf("x=%d\ty=%d\tz=%d\n",x,y,z)

int x, y, z;

main()
{
    x = y = z = 1;
    ++x || ++y && ++z; PRINT3(x,y,z);  
    x = y = z = 1;
    ++x && ++y && ++z; PRINT3(x,y,z);  
    x = y = z = 1;
    ++x &+y && ++z; PRINT3(x,y,z);  
    x = y = z = -1;
    ++x && ++y && ++z; PRINT3(x,y,z);  
    x = y = z = -1;
    ++x || ++y && ++z; PRINT3(x,y,z);  
    x = y = z = -1;
    ++x && ++y && ++z; PRINT3(x,y,z);  
}  
```

(Operators 6.6)
C has a comparatively small set of primitive types. The types may blindly be mixed in expressions, the results governed by a simple hierarchy of conversions. This hierarchy is illustrated in Appendix 4.

For some of the puzzles in this section you will need to know the corresponding integer value of some characters. The tables in Appendix 3 show the values for the characters in the ASCII set. A few of the puzzles yield a different result on the VAX than on the PDP 11. For those puzzles, output from both machines is given.
Basic Types 1: Character, String, and Integer Types

What does the following program print?

```c
#include <stdio.h>

#define PRINT(format,x) printf("x = %format\n",x)

int integer = 5;
char character = '5';
char *string = "5";

main()
{
    PRINT(d,string); PRINT(d,character); PRINT(d,integer);
    PRINT(s,string); PRINT(c,character); PRINT(c,integer=53);
    PRINT(d,( '5'>5 ));
}

{
    int sx = -8;
    unsigned ux = -8;
    PRINT(o,sx); PRINT(o,ux);
    PRINT(o, sx>>3 ); PRINT(o, ux>>3 );
    PRINT(d, sx>>3 ); PRINT(d, ux>>3 );
}
```

(Basic Types 1.1)
Basic Types 1: Character, String, and Integer Types

OUTPUT:

<table>
<thead>
<tr>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>string = an address</td>
<td></td>
</tr>
<tr>
<td>character = 53</td>
<td></td>
</tr>
<tr>
<td>integer = 5</td>
<td></td>
</tr>
<tr>
<td>string = 5</td>
<td></td>
</tr>
<tr>
<td>character = 5</td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>'5'&gt;5 = 1</td>
<td></td>
</tr>
</tbody>
</table>

sx = 177770
ux = 177770
sx>>3 = 177777 or 017777
ux>>3 = 17777
sx>>3 = -1 or 8191
ux>>3 = 8191

sx = 37777777770
ux = 37777777770
sx>>3 = 37777777777 or 03777777777
ux>>3 = 3777777777
sx>>3 = -1 or 536870911
ux>>3 = 536870911

Derivations begin on page 97.

Basic Types 2: Integer and Floating Point Casts

What does the following program print?

```
#include <stdio.h>

#define PR(x) printf("x = %.8g\t",(double)x)
#define NL putchar('n')
#define PRINT4(x1,x2,x3,x4) PR(x1); PR(x2); PR(x3); PR(x4)

int main()
{
  double d;
  float f;
  long l;
  int i;

  i = l = f = d = 100/3; PRINT4(i,l,f,d);
  d = f = l = i = 100/3; PRINT4(i,l,f,d);
  i = l = f = d = 100/3.; PRINT4(i,l,f,d);
  d = f = l = i = (double)100/3;
  PRINT4(i,l,f,d);
  i = l = f = d = (double)(100000/3);
  PRINT4(i,l,f,d);
  d = f = l = i = 100000/3; PRINT4(i,l,f,d);
  d = f = l = i = (double)100000/3;
  PRINT4(i,l,f,d);
}
```
Basic Types 2: Integer and Floating Point Casts

OUTPUT:

- \( i = 33 \quad 1 = 33 \quad f = 33 \quad d = 33 \)
- \( i = 33 \quad 1 = 33 \quad f = 33 \quad d = 33 \)
- \( i = 33 \quad 1 = 33 \quad f = 33.333332 \quad d = 33.333333 \)
- \( i = 33 \quad 1 = 33 \quad f = 33 \quad d = 33 \)
- \( i = \text{overflow} \quad 1 = 33333 \quad f = 33333 \quad d = 33333 \)
- \( i = \text{overflow} \quad 1 = -32203 \quad f = -32203 \quad d = -32203 \)

Derivations begin on page 99.

Basic Types 3: More Casts

What does the following program print?

```c
#include <stdio.h>

#define PRINT(x) printf("x = %g\t",(double)(x))
#define PRINT1(x1) PRINT(x1);
#define PRINT2(x1,x2) PRINT(x1); PRINT1(x2)

main()
{
    double d=3.2, x;
    int i=2, y;

    x = (y=d/i)*2; PRINT2(x,y);
    y = (x=d/i)*2; PRINT2(x,y);

    y = d * (x=2.5/d); PRINT1(y);
    x = d * (y = ((int)2.9+1.1)/d); PRINT2(x,y);
}
```
Basic Types 3: More Casts

**OUTPUT:**

\[
\begin{align*}
x &= 2 & y &= 1 & \text{(Basic Types 3.1)} \\
x &= 1.6 & y &= 3 & \text{(Basic Types 3.2)} \\
y &= 2 & \text{(Basic Types 3.3)} \\
x &= 0 & y &= 0 & \text{(Basic Types 3.4)}
\end{align*}
\]

Derivations begin on page 103.

---

**Included Files**

Each of the remaining programs in this book begins with the preprocessor statement

```c
#include "defs.h"
```

When the programs are compiled, the preprocessor replaces this line with the contents of the file `defs.h`, making the definitions in `defs.h` available for use. Here is a listing of `defs.h`:

```c
#include <stdio.h>
#define PR(format, value) printf("value = \%format\t", (value))
#define NL putchar(\'\n\')
#define PRINT1(f, x1) PR(f, x1), NL
#define PRINT2(f, x1, x2) PR(f, x1), PRINT1(f, x2)
#define PRINT3(f, x1, x2, x3) PRINT1(f, x1), PRINT2(f, x2, x3)
#define PRINT4(f, x1, x2, x3, x4) PRINT1(f, x1), PRINT3(f, x2, x3, x4)
```

defs.h begins with an include statement of its own, calling for the insertion of the file `stdio.h`, as required by the standard C library. The rest of `defs.h` comprises macros for printing. As an example, to print 5 as a decimal number, the `PRINT1` macro could be called by the expression

```c
PRINT1(d, 5)
```

which expands to

```c
PR(d, 5), NL
```

which further expands to

```c
printf("5 = \%d\t", (5)), putchar(\'\n\').
```

The `PRINT` macros point out a feature of the preprocessor that often causes confusion. A macro name that appears inside a string (i.e., enclosed within double quotes) will not be expanded. However, argument names within the body of a macro will be replaced wherever they are found, even inside strings. Notice that the macro `PR` takes advantage of the latter property. See the Preprocessor Section, beginning on page 69, for a more detailed description of macro substitution.
C, as most programming languages, has control constructs for conditional selection and looping. To work the puzzles in this section, you will need to know how to determine the extent of each construct. In a well-formatted program, extent is indicated by indentation. Reading a poorly-formatted program is difficult and error prone; the following puzzles should convince you.
Control Flow 1: if Statement

What does the following program print?

```
#include "defs.h"

main()
{
    int x, y=1, z;

    if( y!=0 ) x=5;
    PRINT1(d,x);  \(\text{(Control Flow 1.1)}\)

    if( y==0 ) x=3;
    else x=5;
    PRINT1(d,x);  \(\text{(Control Flow 1.2)}\)

    x=1;
    if( y<0 ) if( y>0 ) x=3;
    else x=5;
    PRINT1(d,x);  \(\text{(Control Flow 1.3)}\)

    if( z=y<0 ) x=3;
    else if( y==0 ) x=5;
    else x=7;
    PRINT2(d,x,z);  \(\text{(Control Flow 1.4)}\)

    if( z=(y==0) ) x=5; x=3;
    PRINT2(d,x,z);  \(\text{(Control Flow 1.5)}\)

    if( x=z=y ) x=3;
    PRINT2(d,x,z);  \(\text{(Control Flow 1.6)}\)
}
Control Flow 1: if Statement

**OUTPUT:**

- $x = 5$ (Control Flow 1.1)
- $x = 5$ (Control Flow 1.2)
- $x = 1$ (Control Flow 1.3)
- $x = 7$ $z = 0$ (Control Flow 1.4)
- $x = 3$ $z = 0$ (Control Flow 1.5)
- $x = 3$ $z = 1$ (Control Flow 1.6)

Derivations begin on page 105.

Control Flow 2: while and for Statements

What does the following program print?

```c
#include "defs.h"

main()
{
    int x, y, z;
    x = y = 0;
    while( y < 10 ) ++y; x += y;
    PRINT2(d, x, y);  
    (Control Flow 2.1)
    x = y = 0;
    while( y < 10 ) x += ++y;
    PRINT2(d, x, y);  
    (Control Flow 2.2)
    y = 1;
    while( y < 10 ) {
        x = y++; z = ++y;
    }
    PRINT3(d, x, y, z);  
    (Control Flow 2.3)
    for( y = 1; y < 10; y++ ) x = y;
    PRINT2(d, x, y);  
    (Control Flow 2.4)
    for( y = 1; (x == y) < 10; y++ )
    PRINT2(d, x, y);  
    (Control Flow 2.5)
    for( x = 0, y = 1000; y > 1; x++, y /= 10 )
    PRINT2(d, x, y);  
    (Control Flow 2.6)
}
```
Control Flow 2: while and for Statements

**OUTPUT:**

\[
\begin{align*}
&x = 10, y = 10 \quad (\text{Control Flow 2.1}) \\
&x = 55, y = 10 \quad (\text{Control Flow 2.2}) \\
&x = 9, y = 11, z = 11 \quad (\text{Control Flow 2.3}) \\
&x = 9, y = 10 \quad (\text{Control Flow 2.4}) \\
&x = 10, y = 10 \quad (\text{Control Flow 2.5}) \\
&x = 0, y = 1000 \quad (\text{Control Flow 2.6})
\end{align*}
\]

*Derivations begin on page 108.*

---

Control Flow 3: Statement Nesting

What does the following program print?

```c
#include "defs.h"
#define ENUF 3
#define EOS '\0'
#define NEXT(i) input[i++]
#define FALSE 0
#define TRUE 1

char input[]="PI=3.14159, approximately";

main()
{
    char c;
    int done, high, i, in, low;
    i=low=in=high=0;
    while( (c=NEXT(i)) != EOS )
        if( c<'0' ) low++;
            else if( c>'9' ) high++;
            else in++;
    PRINT3(d,low,in,high);
    i=low=in=high=0; done=FALSE;
    while( (c=NEXT(i)) != EOS && !done )
        if( c<'0' ) low++;
            else if( c>'9' ) high++;
            else in++;
        if( low>=ENUF && high>=ENUF && in>=ENUF )
            done = TRUE;
    PRINT3(d,low,in,high);
    i=low=in=high=0; done=FALSE;
    while( (c=NEXT(i)) != EOS && !done )
        if( c<'0' ) done = (++low==ENUF);
            else if( c>'9' ) done = (++high==ENUF);
            else done = (++in==ENUF);
    PRINT3(d,low,in,high);
}
```

(Control Flow 3.1)

(Control Flow 3.2)

(Control Flow 3.3)
Control Flow 3: Statement Nesting

OUTPUT:

<table>
<thead>
<tr>
<th>low</th>
<th>in</th>
<th>high</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>16</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>3</td>
</tr>
</tbody>
</table>

Derivations begin on page 112.

Control Flow 4: switch, break, and continue Statements

What does the following program print?

```c
#include "defs.h"
char input[] = "SSSWI\TECH\1\1\W\1\WALLMP1";

main()
{
    int i, c;
    for( i=2; (c=input[i])!="\0"; i++ ) {
        switch(c) {
            case 'a': putchar('i'); continue;
            case '1': break;
            case 'E': case 'L': continue;
            default: putchar(c); continue;
        }
    }
    putchar( '"' );
}
putchar('\n');
```

(Control Flow 4.1)
Control Flow 4: switch, break, and continue Statements

OUTPUT:

SWITCH SWAMP (Control Flow 4.1)

Derivation begins on page 114.

Much has been written about programming style, about which constructs to avoid and which to imitate. A cursory conclusion from the seemingly diverse advice is that good style is largely a matter of personal taste. A more reasoned conclusion is that good style in programming, as elsewhere, is a matter of good judgement. And while there are many good style guidelines, there are few always appropriate, always applicable style rules.

With this in mind, the following puzzles illustrate a few common style blunders. The solutions given are not so much answers, as in other sections, but rather alternatives. If there is an overall key to good style, it is a recognition of the final two steps in writing a readable program:

- Establish a clear statement of the idea to be coded.
- Develop the structure of the code from the structure of the idea statement.
Programming Style 1: Choose the Right Condition

Improve the following program fragments through reorganization.

while(A) {
    if(B) continue;
    C;
}

while ( (c=getchar())!='\n' ) {
    if( c==' ' ) continue;
    if( c=='\t' ) continue;
    if( c<='0' ) return(OTHER);
    if( c<=9' ) return(DIGIT);
    if( c<='a' ) return(OTHER);
    if( c<='z' ) return(ALPHA);
    return(OTHER);
}
Derivations begin on page 119.

Storage Classes

1. Blocks
2. Functions
3. More Functions
4. Files

Each variable in C possesses two fundamental properties, type and storage class. Type has been covered in an earlier section.

Storage class determines the scope and lifetime for a variable, scope being that part of a program in which a variable is known and lifetime being that portion of an execution during which a variable has a value. The boundaries of scope and lifetime are blocks, functions, and files.
Programming Style 2: Choose the Right Construct

Improve the following program fragments through reorganization.

```c
done=i=0;
while( i<MAXI && !done ) {
    if( (x/=2)>>1 ) { i++; continue; }
    done++;
}

{
    if(A) { B; return; }
    if(C) { D; return; }
    if(E) { F; return; }
    G; return;
}

plusflg=zeroflg=negflg=0;
if( a>0 ) ++plusflg;
if( a==0 ) ++zeroflg;
else if( !plusflg ) ++negflg;

i=0;
while(((c=getchar())!=EOF)){
    if(c=='\n'&&c!='\t'){s[i++]=c;continue;}
    if(c=='\n')break;
    if(c=='\t')c=' ';
    s[i++]=c;}

if( x!=0 )
    if( j>k ) y=j/x;
    else y=k/x;
else
    if( j>k ) y=j/NEARZERO;
    else y=k/NEARZERO;
```

\]

*Derivations begin on page 125*

Storage Classes 4: Files

**What does the following program print?**

```c
#include "defs.h"
int i=1;
main()
{
    auto int i, j;
    i = reset();
    for( j=1; j<=3; j++ ) {
        PRINT2(d,i,j);
        PRINT1(d,next(i);
        PRINT1(d,last(i);
        PRINT1(d,new(i+j));
    }
}
```

*In another file*

```c
static int i=10;
int next()
{
    return( i+=1 );
}
int last()
{
    return( i-=1 );
}
int new(i)
int i;
{ static int j=5;
    return( i=j+=i );
}
```

*In yet another file*

```c
extern int i;
reset()
{
    return(i);
}
```
Pointers and Arrays

1. Simple Pointer and Array
2. Array of Pointers
3. Multidimensional Array
4. Pointer Stew

Pointers have long been abused by programmers and thus maligned in style guides. Specifically, pointers are criticized since, by their nature, it is impossible to identify fully a pointer's referent without backing up to where the pointer was last defined; this adds complexity to a program and makes verification much more difficult.

The C language, rather than restricting the use of pointers, often makes them the natural choice for use. As the following puzzles will illustrate, pointers and arrays are very closely related. For any application using array indexing, a pointer version also exists. The warnings against the dangers of pointer misuse apply as strongly to C as to any language.

Derivations begin on page 127.

Storage Classes 4: Files

**OUTPUT:**

\[
i = 1 \quad j = 1 \quad (\text{Storage Classes 4.1})
\]

next(i) = 11
last(i) = 10

Preprocessor

1. The Preprocessor Doesn't Know C
2. Caution Pays

Though in a strict sense the preprocessor is not part of the C language, few C programs would compile without it. Its two most important functions are macro substitution and file inclusion.

This section concentrates on macro substitution. When used judiciously, macros are a versatile tool that can enhance the readability and efficiency of a program. When used unwisely, macros, like other features in C, can lead to insidious bugs. To solve the puzzles in this section, follow the rules for expanding macros very carefully.
What does the following program print?

```
#include <stdio.h>
#define FUDGE(k) k+3.14159
#define PR(a) printf("a= %d\t",(int)(a))
#define PRINT(a) PR(a); putchar('n')
#define PRINT2(a,b) PR(a); PRINT(b)
#define PRINT3(a,b,c) PR(a); PRINT2(b,c)
#define MAX(a,b) (a<b ? b : a)

main()
{
  {
    int x=2;
    PRINT( x*FUDGE(2) );
  }

  {
    int cel;
    for( cel=0; cel<=100; cel+=50 )
      PRINT2( cel, 9./5*cel+32 );
  }

  {
    int x=1, y=2;
    PRINT3( MAX(x++,y),x,y );
    PRINT3( MAX(x++,y),x,y );
  }
}
```
Preprocessor 1: The Preprocessor Doesn’t Know C

**OUTPUT:**

\[
x \cdot \text{FUDGE}(2) = 7
\]

\[\text{cel} = 0 \quad \text{cel} = 50 \quad \text{cel} = 100 \quad 9.5 \cdot \text{cel} + 32 = 302\]

\[\text{MAX}(x++,y) = 2 \quad x = 2 \quad y = 2\]

\[\text{MAX}(x++,y) = 3 \quad x = 4 \quad y = 2\]

Derivations begin on page 158.

Preprocessor 2: Caution Pays

What does the following program print?

```c
#include <stdio.h>
#define NEG(a) -a
#define weeks(mins) (days(mins)/7)
#define days(mins) (hours(mins)/24)
#define hours(mins) (mins/60)
#define mins(secs) (secs/60)
#define TAB(c,i,oi,t) if(c=='	')
                  for(t=S-(i-oi-1)XS,oi=i; t; t--)
                  putchar(' ');\n
#define PR(a) printf("a= %d\t",(int)(a))
#define PRINT(a) PR(a); putchar(\n')

int x=1;

main()
{
    PRINT( -NEG(x) );
    PRINT( weeks(10080) );
    PRINT( days(mins(86400)) );

    static char input[] = "\twhich\tif?";
    char c;
    int i, oldi, temp;
    for( oldi = -1,i=0; (c=input[i])!='\0'; i++)
    {
        if( c< ' ' ) TAB(c,i,oldi,temp);
        else putchar(c);
    }
    putchar(\n');
}
```

Preprocessor 2: Caution Pays

OUTPUT:

\[-\text{NEG}(x) = 0\]  \hspace{1cm} (Preprocessor 2.1)

\[\text{weeks}(10080) = 1\]  \hspace{1cm} (Preprocessor 2.2)

\[\text{days}(\text{mins}(86400)) = 1\]  \hspace{1cm} (Preprocessor 2.3)

eleven spaces

Derivations begin on page 161.

SOLUTIONS
Operators 1.1

\( x = -3 + 4 \times 5 - 6 \)

Begin by reading the precedence table in Appendix 1 from high to low.

\( x = (-3) + 4 \times 5 - 6 \)

The highest level operator in the expression is the unary -. We'll use parentheses to indicate the order of binding operands to operators.

\( x = (-3) + (4 \times 5) - 6 \)

Next highest in the expression is \(*\).

\( x = ((-3) + (4 \times 5)) - 6 \)

Both + and - are at the same precedence level. The order of binding thus depends on the associativity rule for that level. For + and -, associativity is left to right. First the + is bound.

\( x = (((-3) + (4 \times 5)) - 6) \)

And then the -.

\( x = ((-3) + (4 \times 5)) - 6 \)

And finally, near the bottom of the precedence table, is \(=\). Now that we have completely identified the operands for each operator, we can evaluate the expression.

\( x = ((-3) + (4 \times 5)) - 6 \)

For this expression, evaluation proceeds from the inside out.

\( x = ((-3 + 20) - 6) \)

Replace each subexpression by its resulting value.

\( x = (17 - 6) \)

\( x = 11 \)

11, an integer

The value of an assignment expression is the value of the right-hand side cast in the type of the left-hand side.

About printf. printf is the formatted print routine that comes as part of the standard C library. The first argument to printf is a format string. It describes how any remaining arguments are to be printed. The character % begins a print specification for an argument. In our program, %d told printf to interpret and print the next argument as a decimal number. We will see other print specifications in later programs. printf can also output literal characters. In our program, we “printed” a newline character by giving its name (\n) in the format string.
Operators 1.2

\[ x = 3 + 4 \times 5 - 6 \]
\[ x = 3 + (4 \times 5) - 6 \]
\[ x = (3 + (4 \times 5)) - 6 \]
\[ x = (((3 + (4 \times 5)) - 6)) \]
\[ x = (((3 + 4) - 6)) \]
\[ x = (7 - 6) \]
\[ x = 1 \]

This expression is very similar to the previous one. Following precedence and associativity leads to this. (The modulo, \( \% \), operator yields the remainder of dividing 4 by 5.)

Again, evaluation is from the inside out.

Operators 1.3

\[ x = -3 \times 4 \times 6 / 5 \]
\[ x = (-3) \times 4 \times (-6) / 5 \]
\[ x = ((-3) \times 4) \times (-6) / 5 \]
\[ x = ((((-3) \times 4) \times (-6)) / 5) \]
\[ x = (((((-3) \times 4) \times (-6)))) / 5) \]
\[ x = ((((-3) \times 4) \times (-6)) / 5) \]
\[ x = ((((-3) \times 4) \times (-6)) / 5) \]
\[ x = ((-12 \times -6) / 5) \]
\[ x = (0 / 5) \]
\[ x = 0 \]

This expression is a bit more complex than the last, but rigorous adherence to precedence and associativity will untangle it. \(+, \times, \text{ and } / \text{ are all at the same precedence level, and they associate from left to right.}\)

Evaluating from the inside out.

Operators 1.4

\[ x = (7 + 6) \times 5 / 2 \]
\[ x = (7 + 6) \times 5 / 2 \]
\[ x = ((7 + 6) \times 5) / 2 \]
\[ x = (((7 + 6) \times 5) / 2) \]
\[ x = ((7 + 6) \times 5) / 2) \]
\[ x = ((7 + 6) \times 5) / 2) \]
\[ x = (3 / 2) \]
\[ x = 1 \]

Of course we are not totally at the mercy of predefined precedence. Parentheses can always be used to effect or clarify a meaning.

Subexpressions within parentheses bind first.

Then, it is according to the precedence and associativity rules as before.

Evaluating.

Integer arithmetic truncates any fractional part.

About programming style. As mentioned in the Preface, the programs in this book are not models to be copied. They were designed to make you think about the mechanics of how C works. But the puzzles do contain messages about program style. If a construct always forces you to consult a reference to find out how some detail is handled, then the construct is either not well written or it should be accompanied by a comment that provides the missing details.

The message from this first set of puzzles is to use parentheses in complex expressions to help the reader associate operands with operators.
Operators 2.1

Initially \( x=2 \)
\[ x \star\star 3 + 2 \]
\[ x \star\star (3+2) \]
Again follow the precedence table.
As we saw earlier, the assignment operators have lower precedence than the arithmetic operators. (\( \star\star \) is an assignment operator.)
\[(x\star\star(3+2))\]
\[(x=5)\]
Evaluating.
\[(x=x\star 5)\]
Expanding the assignment to its equivalent form.
\[(x=10)\]
\[10\]

About \textit{define}. This program begins with the line
\
\begin{verbatim}
#define PRINTX printf("%d\n",x)
\end{verbatim}

Any line in a C program that begins with the character \# is a statement to the C preprocessor. One job done by the preprocessor is the substitution of one string by another. The \textit{define} statement in this program tells the preprocessor to replace all instances of the string \textit{PRINTX} with the string \textit{printf("%d\n",x)}.

Operators 2.2

Initially \( x=10 \)
\[ x \star\star y = z = 4 \]
\[ x \star\star y = (z=4) \]
In this expression all the operators are assignments, hence associativity determines the order of binding. Assignment operators associate from right to left.
\[(x\star\star(y=(z=4)))\]
\[(x\star\star(y=4))\]
\[(x\star\star=4)\]
\[40\]

Operators 2.3

Initially \( y=4, z=4 \)
\[ x = y \star\star z \]
\[ x = (y\star\star z) \]
Often a source of confusion for programmers new to C is the distinction between \( \star\star \) (assignment) and \( \star\star\) (test for equality). From the precedence table it can be seen that \( \star\star \) is bound before \( \star\star\).
\[(x=(y\star\star z))\]
\[(x=(TRUE))\]
\[(x=1)\]
\[1\]

Relational and equality operators yield a result of \textit{TRUE}, an integer 1, or \textit{FALSE}, an integer 0.
Operators 2.4

Initially \( x=1, z=4 \)
\[
x == ( y = z )
\]
\[
(x == (y == z))
\]
\[
(x == 4)
\]
FALSE, or 0

In this expression the assignment has been forced to have higher precedence than the test for equality through the use of parentheses.

Evaluating.

The value of the expression is 0. Note however that the value of \( x \) has not changed (\( == \) does not change its operands), so PRINT prints 1.

Operators 3.1

Initially \( x=2, y=1, z=0 \)
\[
x = x && y || z
\]
\[
x = (x && y) || z
\]
\[
x = (x && y) || z
\]
\[
(x = ( (x && y) || z ))
\]
\[
(x = ((TRUE && TRUE) || z ))
\]
\[
(x = (TRUE || z))
\]
\[
(x = (TRUE || whatever))
\]
\[
(x = TRUE)
\]
\[
(x = 1)
\]
1

Bind operands to operators according to precedence.

Logical operators are evaluated from left to right. An operand to a logical operator is FALSE if it is zero and TRUE if it is anything else.

The logical AND, \( && \), yields TRUE only when both its operands are TRUE, otherwise FALSE.

Once one argument to the OR, \( || \), is known to be TRUE we know the result of the \( || \) will be TRUE regardless of the other operand. Hence there is no need to evaluate the expression further.

More about define. The define statement that begins this program is a little fancier than that in the previous program. Here, PRINT is the name of a macro with arguments, not just a simple string. The preprocessor performs two levels of substitution on macros with arguments: first the actual arguments are substituted for the formal arguments in the macro body, and then the resulting macro body is substituted for the macro call.

For example, in this program PRINT has one formal argument, int. PRINT\( (x) \) is a call of PRINT with the actual argument \( x \). Thus, each occurrence of int in the macro body is first replaced by \( x \), and then the resulting string, printf("%d\n", x), is substituted for the call, PRINT\( (x) \). Notice that the formal parameter int did not match the middle letters in printf. This is because the formal arguments of a macro are identifiers; int only matches the identifier int.
Operators 3.2

Initially \( x=1, y=1, z=0 \)

\[
x++(\text{true}&&((\text{true}&&z)))
\]

Binding operands to operators.

\[
(x++(\text{true}&&z))
\]

Evaluating from left to right.

\[
(x++(\text{true}&&z))
\]

TRUE, or 1

Operators 3.3

Initially \( x=1, y=1 \)

\[
z=x++-1
\]

Following precedence.

\[
z=((x++)-1)
\]

The ++ to the right of its operand is a post increment. This means that \( x \) is incremented after its value is used in the expression.

\[
(z=0)
\]

0

Operators 3.4

Initially \( x=2, y=1, z=0 \)

\[
z+=-(x++)+(++y)
\]

Unary operators associate from right to left, thus ++ binds before unary -. (Actually, the expression would not be legal if it were arranged so that the - bound first since ++ and - - expect a reference to a variable (an lvalue) as their operand. \( x \) is an lvalue, but \(-x \) is not.)

\[
z+=((-x++)+(++y))
\]

Evaluating from the inside out.

\[
(z=0)
\]

0

Operators 3.5

Initially \( x=3, z=0 \)

\[
z=x/(++x)
\]

You may be tempted at this point to begin evaluating this expression as before, from the inside out. First the value of \( x \) would be retrieved and incremented to be divided into the value of \( x \). One question that might be asked is what value is retrieved from \( x \) for the numerator, 3 or 4? That is, is the value for the numerator retrieved before or after the increment is stored? The C language does not specify when such a side effect\(^1\) actually occurs; that is left to the compiler writer. The message is to avoid writing expressions that depend upon knowing when a side effect will occur.

---

\(^1\) A side effect is any change to the state of a program that occurs as a byproduct of executing a statement. By far the most common side effects in C relate to storing intermediate values in variables, such as with the increment operator as above or with an embedded assignment operator.
Operators 4.1

Initially $x=03$, $y=02$, $z=01$

$x \mid y \& z$

Integer constants preceded by 0 (zero) are octal values. Octal notation is particularly useful when working with the bitwise operators because it is easy to translate octal numbers to binary. In this problem, 01, 02, and 03 are equivalent to 1, 2, and 3, so using octal is merely a cue to the reader that the program will deal with the values of $x$, $y$, and $z$ as bit strings.

Following precedence.

The innermost expression is evaluated first.

In binary, $01=1$, $02=10$, $03=11$

Investigate

03

03

00

1 11

---

11

Operators 4.2

Initially $x=03$, $y=02$, $z=01$

$x \mid y \& -z$

$(x \mid (y \& (-z)))$

$(x \mid (y \& -01))$

$(x \mid (02 \& -01))$

$(03 \mid 02)$

- complements each of the bits of its operand. Thus $0\ldots01$ becomes $1\ldots10$.

In binary,

\[
\begin{array}{c}
0\ldots010 \\
& 1\ldots110 \\
& 0000010
\end{array}
\]

In binary,

10

1 11

---

11

Operators 4.3

Initially $x=03$, $y=02$, $z=01$

$x \wedge y \& -z$

$(x \wedge (y \& (-z)))$

$(x \wedge (02 \& -01))$

$(03 \wedge 02)$

This is the same as the previous problem except that the exclusive or, $\wedge$, has been substituted for the inclusive or, $\mid$.

In binary,

10

^ 11

---

01
**Operators 4.4**

Initially \( x = 03, y = 02, z = 01 \)

\[ x \& y \& \& z \]

\[ ((x\&y)\&\&z) \]

\[ ((03\&02)\&\&z) \]

\[ (02\&\&z) \]

\[ (TRUE\&\&z) \]

\[ (TRUE\&\&01) \]

\[ (TRUE\&\&TRUE) \]

**TRUE**, or \( 1 \)

**Operators 4.5**

Initially \( x = 01 \)

\[ 1 \cdot x \cdot \cdot \cdot \]

\[ (1\cdot x)\cdot \cdot \cdot \]

\[ (1TRUE)\cdot \cdot \cdot \]

\[ (FALSE)\cdot \cdot \cdot \]

\[ (01\cdot \cdot \cdot) \]

\[ 1 \]

\&\& yields **TRUE** whenever both operands are **TRUE**.

**Operators 4.6**

Initially \( x = 01 \)

\[ -x \cdot x \]

\[ ((-x)\cdot x) \]

\[ (-01\cdot 01) \]

\[ -1 \]

In binary,

\[ 1\ldots110 \]

\[ 10\ldots001 \]

\[ 1\ldots111, \text{ or } -1 \]

(The answer is the same for all values of \( x \). Actually, it is \(-1\) on a two's-complement machine, like the PDP-11. On a one's-complement machine \( 1\ldots1 \) would be 1. For the few cases in this book where it matters, two's-complement will be used.)

**Operators 4.7**

Initially \( x = 01 \)

\[ x \cdot x \]

\[ (01\cdot 01) \]

\[ 0 \]

In binary,

\[ 0\ldots01 \]

\[ ^{0\ldots01} \]

\[ -0\ldots00 \]

(The answer is the same for all values of \( x \).)
Operators 4.8

Initially \( x = 01 \)
\[ x << 3 \]
\[ x = 01 << 3 \]
\[ x = 8 \]
In binary,
\[
\begin{align*}
0000 \ldots 01 \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
0 \ldots 01000, \text{ which is } 8
\end{align*}
\]
Each place shifted to the left is an effective multiplication by 2.

Operators 4.9

Initially \( y = -01 \)
\[ y << 3 \]
\[ y = -01 << 3 \]
\[ y = -8 \]
In binary,
\[
\begin{align*}
1111 \ldots 11 \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
1 \ldots 11000, \text{ or } -8
\end{align*}
\]

Operators 4.10

Initially \( y = -08 \)
\[ y >>> 3 \]
\[ y = -08 >>> 3 \]

It is tempting at this point to assume that \( y = -1 \). Unfortunately this is not always the case, since the computer may not preserve the sign of a number when shifting. C does not guarantee that the shift will be arithmetically correct. In any case, there is a much clearer way to divide by 8, namely \( y = y / 8 \).

Operators 5.1

Initially \( x = 3, y = 2, z = 1 \)
\[
\begin{align*}
x < y ? y : x \\
( x < y ) ? ( y ) : ( x ) \\
(( x < y ) ? ( y ) : ( x )) \\
( (x) ) \\
( 3 )
\end{align*}
\]
The conditional operator, aside from taking three operands, is parsed like any other operator.

First the condition is evaluated. Then either the true part or the false part is evaluated, but not both.

In this problem the value of the condition is FALSE, thus the value of the conditional expression is the value of the false part.

Operators 5.2

Initially \( x = 3, y = 2, z = 1 \)
\[
\begin{align*}
x < y ? x ++ : y ++ \\
( x < y ) ? ( x ++ ) : ( y ++ ) \\
(( x < y ) ? ( x ++ ) : ( y ++ )) \\
( (y++) ) \\
( 2 ), \text{ and } y = 3
\end{align*}
\]

First evaluate the condition.

The condition is FALSE so the false part is evaluated.

(And since \( x ++ \) was not evaluated, \( x \) remains 3.)
Operators 5.3

initially x=3, y=3, z=1
z += x < y ? x ++ : y ++
(z += ((z < y) ? (x++) : (y++)))
(z += (FALSE ? (x++) : (y++)))
(z += (y++))

(z = (3)), and y=4
(z = z + 3)
(z = 4)
4

Operators 5.4

initially x=3, y=4, z=4
(z >= y >= x) ? 1 : 0
(((z >= y) >= x) ? (1) : (0))
((TRUE >= x) ? (1) : (0))
((1 >= x) ? (1) : (0))

(FALSE ? (1) : (0))
((0))
0

The result of the conditional expression is the right-hand side of the assignment.

Operators 5.5

initially x=3, y=4, z=4
z >= y & y >= x
((z >= y) & (y >= x))
(TRUE & (y >= x))
(TRUE & TRUE)
(TRUE)
1

Evaluating from left to right.

The condition is evaluated from the inside out.

The value of the innermost relation is TRUE. It is compared to the integer x. While this is legal in C, it is really playing footloose with the value TRUE being an integer 1, and, as in this problem, it is usually not what's wanted. (The next puzzle shows the right way to compare three values.)
Operators 6.1

initially \( x=1, y=1, z=1 \)

\(++x\) \&\& \(++y\) \&\& \(++z\)

\(((++x)\|((++y)\&(++z)))\)

\((2\|((++y)\&(++z)))\), and \(x=2\)

\((TRUE\|\)whatever\)

Binding operands to operators.

Evaluating from left to right.

Since the left operand of the \( \| \) is \( TRUE \), there is no need to evaluate further. In fact, C guarantees that it will \textit{not} evaluate further. The rule is that a logical expression is evaluated from left to right until its truth value is known. For this problem that means \( y \) and \( z \) remain 1.

\( TRUE \), or 1

Operators 6.2

initially \( x=1, y=1, z=1 \)

\(++x\) \&\& \(++y\) \&\& \(++z\)

\(((++x)\&\&((++y))\|((++z)))\)

\((2\&\&((++y))\|((++z)))\), and \(x=2\)

\((TRUE\&\&((++z)))\)

\( TRUE\|\)whatever

\( TRUE \), or 1

Operators 6.3

initially \( x=1, y=1, z=1 \)

\(++x\) \&\& \(++y\) \&\& \(++z\)

\(((++x)\&\&((++y))\|((++z)))\)

\((2\&\&((++y))\|((++z)))\), and \(x=2, y=2\)

\((TRUE\&\&((++z)))\)

\( TRUE\&\&TRUE\), and \(z=2\)

\( TRUE \), or 1

Operators 6.4

initially \( x=-1, y=-1, z=-1 \)

\(++x\) \&\& \(++y\) \&\& \(++z\)

\(((++x)\&\&((++y))\|((++z)))\)

\((0\&\&((++y))\|((++z)))\), and \(x=0\)

\((FALSE\&\&((++y))\|((++z)))\)

\((FALSE\|((++z)))\)

\( FALSE\|\)whatever

\( FALSE \), or 1

There is no need to evaluate \(++y\) since the left operand to \&\& is \( FALSE \). The value of the \( \| \) operation is still not known, however.

\( FALSE\|\)whatever

\( FALSE \), or 0

\textit{About evaluation order and precedence}. For most operators, the order of evaluation is determined by precedence. As can be seen from the puzzles in this section, there are a few exceptions to this general rule:

- Pre- increment and decrement operators are always evaluated before their operand is considered in an expression.
- Post- increment and decrement operators are always evaluated after their operand is considered.
Operators 6.5

initially \( x = -1, y = -1, z = -1 \)

\[ ++x \quad ++y \quad \& \quad ++z \]
\[ (((x)))(++y)\quad\&\quad((z)) \]
(\(FALSE\quad((++y)\quad\&\quad((++z))\), and \(x=0\)
(\(FALSE\quad((FALSE\quad\&\quad((++z))\)), and \(y=0\)
(\(FALSE\quad\&\quadFALSE\)
\(FALSE\), or \(0\)

Operators 6.6

initially \( x = -1, y = -1, z = -1 \)

\[ ++x \quad \& \quad ++y \quad \& \quad ++z \]
\[ (((++x))\quad\&\quad((++y))\quad\&\quad((++z)) \]

((\(FALSE\quad\&\quad((++y))\quad\&\quad((++z))\)), and \(x=0\)
(\(FALSE\quad\&\quad((++z))\))
\(FALSE\), or \(0\)

About side effects in logical expressions. As you have surely learned by now, the evaluation of a logical expression can be tricky in C because the right-hand part of the expression is evaluated conditionally on the value of the left-hand part. Actually, conditional evaluation is a useful property of the logical operators. The trouble arises when the right-hand part of a logical expression contains a side effect; sometimes the side effect will occur and sometimes it won't. So, while in general it is good practice to use side effects carefully, it is vital in logical expressions.

Basic Types 1.1

\(\text{PRINT}(d, '5')\)
%\(d\) format instructs printf to print the argument as a decimal number. "5" is a pointer to a character array (i.e., the address of the two character array '5' , '0').

\(\text{PRINT}(d, '5')\)
%\(d\) causes the decimal value of the character '5' to be printed.\(^1\)

\(\text{PRINT}(d, 5)\)
The integer 5 is printed in decimal.

\(\text{PRINT}(a, '5')\)
%\(a\) format instructs printf that the argument is a pointer to a character array. Since "5" is a pointer to a character array, the content of that array, 5, is printed.

\(\text{PRINT}(c, '5')\)
%c format instructs printf to translate the argument into the character its value represents. Since "5" is the encoded value for 5, 5 is printed.

\(\text{PRINT}(c, 53)\)
As seen earlier, the decimal number 53 is the ASCII code value for the character 5.

\(\text{PRINT}(d, ('5'>5))\)
One last time. '5' has the integer value 53 which is greater than the integer 5.

---

1. The value given here is that for the ASCII character code (see Appendix 3). The ASCII code is but one of several codes used by computers to represent characters. It will be used in this book for those few cases where it matters.
Basic Types 1.2

Initially sx=-8, ux=-8

```
PRINT(o,sx)  %o instructs printf to print the argument as an octal number.
PRINT(o,ux)  The value -8 is a string of 1's and 0's just as valid for
PRINT(o,sx>>3) unsigned variables as for signed ones.
PRINT(o,ux>>3) We have seen this problem earlier. With some
PRINT(d,sx>>3) versions of C, right shifting of a signed integer causes
PRINT(d,ux>>3) the sign bit to be copied into the vacated high order
PRINT(d,sx>>3) bits, thus having the desirable property of preserving
PRINT(d,ux>>3) sign. Beware—this is compiler dependent!
```

```
PRINT(o,ux>>3) When right shifting an unsigned integer the high
PRINT(d,sx>>3) order bits are always filled with 0's.
PRINT(d,sx>>3) In decimal, right shifting a signed -8 three places
PRINT(d,ux>>3) yields the expected -1 if sign is preserved, 8191
PRINT(d,ux>>3) otherwise (in two's-complement on a 16-bit machine).
PRINT(d,ux>>3) For an unsigned -8, the result is always 8191 (on a
```

Basic Types 2.1

```
i = 1 = f = d = 100/3
(i = (1 = (f = (d = (100/3)))) )
(i = (1 = (f = (d = 33))) )
(i = (1 = (f = (double)33))) , and d = 33
(i = (1 = (float)33)) , and f = 33
(i = (long)33), and l = 33
(integer)33, and i = 33
33, an integer
```

Evaluation is from right to left.
Since both 100 and 3 are integers, the division is integer division and
thus the quotient is truncated.
Recall that the value of an assignment expression is the value of the right-hand side cast in the
type of the left-hand side.

Basic Types 2.2

```
d = f = l = i = 100/3
(d = (f = (l = (i = (100/3)))))
(d = (f = (l = (integer)33))) , and i = 33
(d = (f = (long)33)) , and l = 33
(d = (float)33) , and f = 33
((double)33) , and d = 33
33, a double
```
Basic Types 2.3

\[
i = l = f = d = 100/3. \\
(i = (l = (f = (d = (100/3.)))))) \\
(i = (l = (f = (double)33.333333))) \\
\text{and } d = 33.333333 \\
(i = (l = (float)33.333333)) \\
\text{and } f = 33.333333 \\
\text{3. is a double so the quotient retains its precision.} \\
\text{The printf specification in this program is "%.8g", which tells printf to output numbers of up to eight significant digits. Seven significant digits is about the limit of precision for floats on the PDP-11 and VAX, so the eighth digit is unreliable. The number of significant digits is, of course, machine dependent.} \\
\text{The float to long conversion is through truncation.} \\
(i = (long)33.333333), \text{and } l = 33 \\
\text{33, an integer} \\
\text{33333 cannot be represented as a 16-bit signed integer. Most implementations of C will happily permit arithmetic over- or underflow. When your calculations potentially push the limits of your machine, it is wise to insert explicit range checks.} \\
\text{33333, an integer, or overflow} \\
\]

Basic Types 2.4

\[
d = f = l = i = (double)100/3 \\
(d = (f = (l = (i = ((double)100)/3)))) \\
(d = (f = (l = (i = 33.333333))) ) \\
\text{and } i = 33 \\
(d = (f = (long)33)), \text{and } l = 33 \\
(d = (float)33), \text{and } f = 33 \\
((double)33), \text{and } d = 33 \\
33, \text{a double} \\
\]

Basic Types 2.5

\[
i = l = f = d = (double)(100000/3) \\
(i = (l = (f = (d = ((double)(100000/3)))))) \\
(i = (l = (f = (d = (double)33333)))) \\
d = 33333 \\
\text{The operand to the type cast is the quotient from the integer division of 100000 by 3.} \\
(i = (l = (f = (double)33333))), \text{and } d = 33333 \\
(i = (l = (float)33333)), \text{and } f = 33333 \\
(i = (long)33333), \text{and } l = 33333 \\
((integer)33333), \text{and } i = 33333 \text{ or overflow} \\
\text{The operand to the type cast is the quotient from the integer division of 100000 by 3.} \\
\text{The printf specification in this program is "%.8g", which tells printf to output numbers of up to eight significant digits. Seven significant digits is about the limit of precision for floats on the PDP-11 and VAX, so the eighth digit is unreliable. The number of significant digits is, of course, machine dependent.} \\
\text{The float to long conversion is through truncation.} \\
\text{33333 cannot be represented as a 16-bit signed integer. Most implementations of C will happily permit arithmetic over- or underflow. When your calculations potentially push the limits of your machine, it is wise to insert explicit range checks.} \\
\text{33333, an integer, or overflow} \\
\]
Basic Types 2.6

\[ d = f = 1 = i = \frac{100000}{3} \]
\[(d = (f = (i = \frac{100000}{3})))\]
\[(d = (f = (i = \text{integer}33333)))\]
and \(i = 33333\), or overflow

\[(d = f = (\text{long})-32203)\]
and \(i = -32203\)

\[(d = \text{float})-32203\), and \(f = -32203\)
\[((\text{double})-32203\), and \(d = -32203\)
\[-32203\), a double\]

As we've seen before, 33333 is overflow for a 16-bit signed integer. For integer representations with more bits, \(i\) would get 33333, as would \(d\) and \(f\). We'll continue with the case for 16-bit integers.

The result of an operation that leads to overflow is a legitimate number, just not the number expected. The 33333 is lost, regardless of future type casts.

About numbers. The treatment of numbers is not one of C's strong points. C does not provide a way to catch arithmetic errors even if the hardware so obliges. The range of the numerical data types is fixed by the compiler writer; there is no way to specify a range in the language. To achieve range checking, about the best one can do is explicitly test the value of variables at critical points in a calculation.

Basic Types 3.1

Initially \(d = 3.2\), \(i = 2\)
\(x = (y = d/i)*2\)
\((x = (y = 3.2/2) * 2)\)
\((x = (y = 1.6) * 2)\)
\((x = 1*2), \text{ and } y = 1\)
\((x = 2)\)
\(2, \text{ and } x = 2\)

Initially \(d = 3.2\), \(i = 2\)
\(y = (x = d/i)*2\)
\((y = (x = 1.6) * 2)\)
\((y = 1.6 * 2), \text{ and } x = 1.6\)
Since \(x\) is a double, the result of the assignment is a double.
\((y = 3.2)\)
\(1.6, \text{ a double, determines the type of the product}\)
\(3, \text{ and } y = 3\)
\(y, \text{ an int, gets 3.2 truncated}\)
Basic Types 3.3

Initially d=3.2, i=2
\[ y = d \ast (x=2.5/d) \]
\[ (y = d \ast (x=2.5/d)) \]
\[ (y = d+2.5/d), \text{ and } x=2.5/d \]
\[ (y=2.5) \]
\[ 2, \text{ and } y=2 \]

x is a double, so the precision of \( 2.5/d \) is retained.

y gets 2.5 truncated.

Basic Types 3.4

Initially d=3.2, i=2
\[ x = d \ast (y = (\text{int})2.9+1.1)/d) \]
\[ (x = d \ast (y=(2+1.1)/d)) \]
\[ (x = d \ast (y=3.1/d)) \]
\[ (x = d \ast (y=\text{something})) \]
\[ (x=d+0), \text{ and } y=0 \]

0, and x=0

About mixing types. By now you have seen enough examples of how mixing floating point and integer values in expressions can lead to surprises. It is best to avoid arithmetic with operands of mixed type. If you do need it, make the type conversions explicit by carefully using casts.

Control Flow 1.1

Initially y=1
\[ \text{if}(y=0) x=5; \]
\[ (y=0) \]
\[ \text{TRUE} \]
\[ x=5 \]

The first step is to evaluate the condition.

Since the condition is TRUE, the true part of the if statement is executed.

Control Flow 1.2

Initially y=1
\[ \text{if}(y=0) x=3; \text{ else } x=5; \]
\[ (y=0) \]
\[ \text{FALSE} \]
\[ x=5 \]

Evaluate the condition.

Execute the false part of the if statement.
Control Flow 1.3

Initially $y = 1$

$x = 1$

if ($y < 0$) if ($y > 0$) $x = 3$;
else $x = 5$;

$x = 1$

if ($y < 0$)

  if ($y > 0$) $x = 3$;
  else $x = 5$;

if ($y < 0$)

  $x = 7$;

FALSE

The condition of the first if is FALSE, thus the false part is skipped. The else clause is contained in the true part of the first if since it belongs to the second if. The rule in C is that an else clause belongs to the closest if that can accept it.

Control Flow 1.4

Initially $y = 1$

if ($z < y < 0$) $x = 3$;
else if ($y == 0$) $x = 5$;
else $x = 7$;

$z = (y < 0)$

$z = (1 < 0)$

$z = \text{false}$

FALSE, and $z = 0$

$y = 0$

The true part of an if is the single statement or block following the condition for the if.

Control Flow 1.5

Initially $y = 1$

if ($z = (y == 0)$) $x = 5$; $x = 3$

if ($z = (y == 0)$) {
  $x = 5$;
  $x = 3$;
}

$z = (y == 0)$

$z = \text{false}$

FALSE, and $z = 0$

$x = 3$

The true part of the if is the single statement or block following the condition for the if.

Control Flow 1.6

Initially $y = 1$

if ($x = z = y$); $x = 3$;

if ($x = z = y$) {
  $x = 3$;

  $x = (z = y)$

  $x = (z = 1)$

  $x = 1$}, and $z = 1$

TRUE, and $x = 1$

$x = 3$

The true part of the if is a null statement.

The if condition is TRUE, so the true part of the if is executed. The true part is a null statement and has no effect. Finally, the statement following the if is executed.
while y<10 ++y; x += y;

while y<10 ++y;

y = 0

++y

y = 0 through 9 in the loop

y = 0 on exit

x = 0+10

x = 10

Begin by analyzing the factors that control the execution of the while statement:

The loop condition. The body of the loop is executed as long as the loop condition evaluates to TRUE.

The exit condition. The exit condition, the negation of the loop condition, is TRUE upon a normal termination of the loop.

The initial value of the control variable. This is the value of the control variable during the first iteration of the loop body.

The effect on the control variable of executing the body of the loop.

y = 0 the first time in the loop. Each time through the body y is incremented by 1.

When y = 10 the loop condition evaluates to FALSE and the iteration terminates.

Control passes to the statement following the loop body.

Control Flow 2.2

initially x=0, y=0

while (y<10) x += ++y;

( y<10 )

( y>=10 )

y = 0

x = 55

y = 10 on exit

Control Flow 2.3

initially y=1

while (y<10) { x = y++; z = ++y; }

( y<10 )

( y>=10 )

y = 1

y++, ++y

y = 1, 3, 5, 7, 9 in the loop

x = 1, 3, 5, 7, 9

z = 3, 5, 7, 9, 11

y = 11 on exit

The loop condition.

The exit condition.

The initial value of the control variable.

The effect of the loop on the control variable.

As in the previous problem.

x gets the sum of the values of y (after y is incremented) in the loop.

The sum of the integers 1 to 10.
**Control Flow 2.4**

\[
\text{for}( y=1; y<10; y++ ) x=y;
\]

- The `for` statement aggregates the controlling factors of the loop.
- Loop condition.
- Exit condition.
- Initial value.
- Effect.

\[
y<10
\]

\[
y>=10
\]

\[
y=1
\]

\[
y++
\]

\[
y = 1 \text{ through } 9 \text{ in the loop}
\]

\[
x = 1 \text{ through } 9
\]

\[
y = 10 \text{ on exit}
\]

\[
x \text{ gets the value of } y \text{ in the body of the loop.}
\]

**Control Flow 2.5**

\[
\text{for}( y=1; (x=y)<10; y++ ) ;
\]

- Loop condition.
- Exit condition.
- Initial value.
- Effect.

\[
y<10
\]

\[
y>=10
\]

\[
y=1
\]

\[
y++
\]

\[
y = 1 \text{ through } 9 \text{ in the loop}
\]

\[
x = 1 \text{ through } 10
\]

\[
y = 10 \text{ on exit}
\]

\[
x \text{ gets the value of } y \text{ just before the evaluation of the loop condition. Note that the condition is evaluated one time more than the body is executed.}
\]

**Control Flow 2.6**

\[
\text{for}( x=0,y=1000; y>=1; x++,y/=10 )
\]

- Loop condition.
- Exit condition.
- Initial value.
- Effect.

\[
y>1
\]

\[
y<=1
\]

\[
y=1000
\]

\[
y/=10
\]

\[
y = 1000,100,10 \text{ in the loop}
\]

\[
x = 0,1,2 \text{ in the loop}
\]

\[
y = 1 \text{ on exit}
\]

\[
x = 3 \text{ on exit}
\]

- \( x=0 \) from the `for` statement initialization. \( x \) is incremented after the body and before the test. (The `PRINT2` statement is in the body.)
Control Flow 3.1

Initially $i = \text{in} = h = \text{low} = 0$, input = "PI = 3.14159, approximately"

while ( $c = (\text{NEXT}(i)) \neq \text{EOS} $ )

if ( $1 < '0' $ ) $\text{low}++$

The loop condition effectively is $\text{NEXT}(i) \neq \text{EOS}$, where $\text{NEXT}(i)$ successively takes on the character values from input. $c$ gets the truth value of $\text{NEXT}(i) \neq \text{EOS}$, which, by definition, is $\text{TRUE}$ in the loop and $\text{FALSE}$ on exit.

Control Flow 3.2

Initially $i = \text{in} = h = \text{low} = 0$, done = $\text{FALSE}$, input = "PI = 3.14159, approximately"

while ( $c = (\text{NEXT}(i)) \neq \text{EOS} \& \& \text{done}$ )

$\text{if} ( 'P' < '0' )$

The first time through the loop $c = 'P'$, hence the if condition is $\text{FALSE}$.

else $\text{if} ( 'P' > '9' )$

$\text{true}$, and $\text{high}++$

while ( '$I'$ = EOS $\& \& \text{done}$ )

$\text{done} = (++\text{high} = \text{ENUF})$

The iteration continues until all the characters in input have been read. C uses the ASCII null character, $00$, as the end of string marker.

Control Flow 3.3

Initially $i = \text{in} = h = \text{low} = 0$, done = $\text{FALSE}$, input = "PI = 3.14159, approximately"

while ( $(c = \text{NEXT}(i)) \neq \text{EOS} \& \& \text{done}$ )

if ( '$P' < '0' )

$\text{high}$, after being incremented, is not equal to ENUF, so done is assigned $\text{FALSE}$. $\text{high} = 1$.

else if ( '$P' > '9' )

$\text{true}$.

done = $(++\text{high} = \text{ENUF})$

while ( '$I'$ = EOS $\& \& \text{done}$ )

if ( '$I' < '0' )

$\text{true}$.

done = $(++\text{high} = \text{ENUF})$

while ( '$1'$ = EOS $\& \& \text{done}$ )

if ( '=' < '0' )

$\text{true}$.

done = $(++\text{high} = \text{ENUF})$

while ( '$3'$ = EOS $\& \& \text{done}$ )

$\text{done} = \text{TRUE}$, so 

$\text{done} = \text{FALSE}$, and the loop terminates.
### Control Flow 4.1

```c
char input[] = "SSSWILTECH1\1\11W\1WALLMP1";  
for(i=2; (c=input[i]) != '\0'; i++) {  
    c takes character values from input beginning at the third character.  
    switch('S') {  
        default: putchar('S'); continue  
    }  
    for( ; (c=input[i]) != '\0'; i++) {  
        switch('W') {  
            default: putchar('W'); continue  
        }  
        switch('L') {  
            case 'L': continue  
        }  
        for( ; (c=input[i]) != '\0'; i++) {  
            switch('1') {  
                default: putchar(' ')  
            }  
        }  
    }  
    case '1': break  
    putchar(' ')  
    for( ; (c=input[i]) != '\0'; i++) {  
        switch('1') {  
            case 1: while((c=input[++i]) != '\1' && c != '\0') {  
                i = 12, c = '\11';  
                i = 13, c = 'W';  
                i = 14, c = '\11';  
                case 9: putchar('S')  
            }  
            case 'E': case '1': continue  
        }  
    }  
    case 'E': case 'L': continue  
}
```

The character array `input` is initialized to the character string "SSS...MP1".

In the for loop:
- `i=5, c='L';`
- `i=6, c='T';`
- `i=7, c='E';`
- `i=8, c='C';`
- `i=9, c='H';`
- `i=10, c='1'.`
- `case 'E': case 'L': continue`

The break statement forces an exit from the innermost enclosing loop or `switch`. In this case, it causes a branch to the statement following the end of the `switch`. A space is printed. Back at the top of the for loop.

The character constant '\n', where `n` is up to four octal digits, yields a character with the octal value `n`. For instance, '\0' yields the ASCII character null, and '\101' the character A.

Case labels may be either character or integer constants. '\1' matches the integer 1 since C automatically coerces char to int.

The exit condition for the while is either `c == '\1'` or end of string. Each time the while test is made, i is incremented by 1, thus, the loop advances i past the characters of `input` to either the next '\1' character or the end of string.

Nothing is printed.

The `while` loop terminates.

The statements from each case follow one another directly; there is no implied `break` between cases. Case 9 follows case 1. S is printed. Cases 'E' and 'L' follow case 9.
for( ; (c=input[15]); i++) {
    Again, back to the top of the for loop.
    if (c='W';
    i=16, c='A';
    i=17, c='L';
    i=18, c='L';
    i=19, c='M';
    i=20, c='P';
    i=21, c='1';
    i=22, c='\0';
    putchar('\n')
}

In the for loop:

    i=15, c='W';
    i=16, c='A';
    i=17, c='L';
    i=18, c='L';
    i=19, c='M';
    i=20, c='P';
    i=21, c='1';
    i=22, c='\0';
    putchar('\n')

    W is printed.
    A is printed.
    Nothing is printed.
    Nothing is printed.
    M is printed.
    P is printed.
    Space is printed.
    The for loop terminates.

Programming Style 1.1

The need for a continue statement can often be eliminated by altering a test condition. The resulting code is sometimes remarkably cleaner.

For this problem, simply negating the test to the if statement will do.

    while(A)
        if(!B) C;

Programming Style 1.2

The do...while is another of the C constructs that can sometimes be replaced to advantage. If either a do...while or a while can be used, the while is always preferred since it has the desirable property that the condition is tested before every iteration of the loop. That the condition is not tested before the first iteration of a do...while loop has been the source of many a program bug.

In this problem, the if and do...while are redundant; they are effecting a while.

    do {
        First, eliminate the continue.
        if(A) { B; C; }
    } while(A);

    while(A) {
        Then replace the do...while and if with a while.
        B; C;
    }
Programming Style 1.3

The problem of deeply nested if statements is well known to most experienced programmers: by the time one gets to the innermost condition the surrounding conditions have been forgotten or obscured. The counter approach is to qualify each condition fully, but this tends to generate long conditions that are obscure from the start. Alas, good judgement must prevail!

Here are two possibilities for this problem:

```c
if( A && B && C ) D;
else if( !A && B && C ) E;
else if( !A && B && !C ) F;
```

or,

```c
if( B )
  if( A && C ) D;
else if( !A && C ) E;
else if( !A && !C ) F;
```

Programming Style 1.4

This problem has a straightforward idea hierarchy:

- while there are more characters on the line
- multiway switch based on character type
  - return ALPHA
  - return DIGIT
  - return OTHER.

This translates easily into C:

```c
while( (c=getchar()) != '\n' ) {  
  if( c>='a' && c<='z' ) return(ALPHA);
  else if( c>='0' && c<='9' ) return(DIGIT);
  else if( c!=' ' && c!='\t' ) return(OTHER);
}
return(EOL);
```

Programming Style 2.1

```
done = i = 0;
while( i<MAXI && !done ) {
  if( (x/=2) > 1 ) i++;
  else done++;
}
```

```
i = 0;
while( i<MAXI && (x/=2)>1 ) i++;  
```

The first observation is that the if...continue construct is effecting an if...else. So make it an if...else!

```
while( i<MAXI && (x/=2)>1 ) i++;
```

Then it becomes clear that

- one loop condition is done equal to FALSE;
- done is FALSE as long as the if condition is TRUE;
- thus, one loop condition is (x/2)>1.
Make it explicit!

```
for( i=0; i<MAXI && (x/=2)>1; i++ ) ;
```

A while statement that is preceded by an initialization and that contains a change of the loop control variable is exactly a for statement.

Programming Style 2.2

There are usually many ways to express an idea in C. A useful guideline is to group ideas into chunks. C provides a hierarchy of packaging for these chunks:

- the lowest level ideas become expressions;
- expressions are grouped together into statements;
- statements are grouped together into blocks and functions.

In this problem there is a two level idea hierarchy. At the lowest level are the expressions B, D, F, and G. They are related as the mutually exclusive cases of a multiway switch. A cohesive representation for a general multiway switch is the if...else if construction.

```
if(A) B;
else if(C) D;
else if(E) F;
else G;
return;
```
Programming Style 2.3

The key observation in this problem is that the underlying structure is a three-way switch with mutually exclusive cases.

```
plusflg = zeroflg = negflg = 0;
if( a>0 ) ++plusflg;
else if( a==0 ) ++zeroflg;
else ++negflg;
```

Programming Style 2.4

```
i = 0;
while( (c=getchar())!=EOF && c!='\n' ) {
    if( c=='\n' && c=='\t' ) {
        s[i++] = c;
        continue;
    }
    if( c=='\t' ) c = ' ';
s[i++] = c;
}
i = 0;
while( (c=getchar())!=EOF && c!='\n' ) {
    if( c=='\t' ) {
        s[i++] = c;
        continue;
    }
    if( c=='\t' ) s[i++] = ' ';
}
i = 0;
while( (c=getchar())!=EOF && c!='\n' ) {
    if( c=='\t' ) s[i++] = c;
    else s[i++] = ' ';
for( i=0; (c=getchar())!=EOF && c!='\n'; i++ )
    if( c=='\t' ) s[i] = c;
else s[i] = ' ';
for( i=0; (c=getchar())!=EOF && c!='\n'; i++ )
    s[i] = c=='\t' ? c : ' ';
```

Reformatting the statements to indicate nesting is a good start. Then look closer at the break and continue statements to see if they are really necessary. The break goes easily by adding the negation of the break condition to the condition for the while.

The first if condition can then be reduced. (c != "\n" is now a loop condition, hence it must always be TRUE in the if test.)

The continue statement is effecting an if...else.

Finally, it is clear that s[i] gets the next character if the character is not a tab, otherwise it gets a space. In other words, the code merely replaces tabs by spaces. The last two versions show this quite clearly while also pointing out the close relationship of the if to the conditional. In this example, the if emphasizes the test for tab and the conditional emphasizes the assignment to s[i]...
Programming Style 2.5

if( j>k ) y = j / (x1=0 ? x : NEARZERO);
else y = k / (x1=0 ? x : NEARZERO);

y = MAX(j,k) / (x1=0 ? x : NEARZERO);

In this problem it is quite clear that x1=0 is not the primary idea; the test simply protects against division by zero. The conditional nicely subordinates the zero check.

A case can be made that the assignment to y is the primary idea, subordinating both tests. (MAX returns the greater of its two arguments.)

In this problem it is quite clear that x1=0 is not the primary idea; the test simply protects against division by zero. The conditional nicely subordinates the zero check.

A case can be made that the assignment to y is the primary idea, subordinating both tests. (MAX returns the greater of its two arguments.)

Storage Classes 1.1

int i=0;

i.0 = 0

(The notation x.n is used to reference the variable x defined at block level n.) The storage class of i.0 is extern. The scope of i.0 is potentially any program loaded with this file. The lifetime of i.0 is the full execution time of this program.

main()
{

auto int i=1;

i.1 = 1 (i at level 1). The storage class of i.1 is auto. The scope of i.1 is the function main. The lifetime of i.1 is the duration of the execution of main.

PRINT1(d,i.1);

When two variables have the same name, the innermost variable is referenced when the name is given; the outer variable is not directly accessible.

{

Block level is now 2.

int i=2;

i.2 = 2.

The storage class of i.2 is auto, the default storage class for variables defined in block 1 or deeper. The scope of i.2 is block 2 and its lifetime is the duration of execution of block 2.

PRINT1(d,i.2);

{

Block level is now 3.

i.2+=1;

i.2 = 3.

PRINT1(d,i.2); i.2 is printed since it is the innermost variable named i.

} Block level returns to 2.

PRINT1(d,i.2); i.2 is printed again.

} Block level returns to 1; i.2 dies.

PRINT1(d,i.1); With the death of i.2, i.1 became the innermost variable named i.

} Block level returns to 0.

1. The block level at any point in the text of a program is the count of left braces ( { ) minus the count of right braces ( } ). In other words, it is the number of textually open blocks. The outermost level of a program, i.e., no blocks open, is block level 0.

2. You might ask why the storage class of i is not explicitly declared here using the extern keyword. Unless declared otherwise, the storage class for variables defined at block level 0 is extern. Tagging a variable with extern does not define the variable. Instead, it tells the compiler that the variable has been defined elsewhere at block level 0.
Storage Classes 2.1

```c
int i=LOW;
main()
{
 auto int i=HIGH;
 reset(i/2);
 PRINT1(d,i.1);
 reset(i.1=i/2);
 PRINT1(d,i.1);
 i.1 = reset(i/2);
 int reset(1)
 {
 (int i=1;
 {i.0 = 0.
 i.1 = 5.
 The function reset is called with the value i.1/2, or 2. Its execution has no effect on i.1.
 reset is again called with i.1/2. This time i.1 is assigned 2 as a side effect of the function call. Again, reset has no effect on i.1.
 i.1 gets the value returned by reset called with i.1/2. We will expand the function call in line.
 The type of the value returned by a function is specified in its declaration. reset returns a value of type int.
 i.reset = 1.
 Parameters in a function behave like initialized local variables. We indicate these implied assignments by surrounding them with parentheses.
 i.reset = i.reset<=2 ? 5 : 2; i.reset = 5.
 return(i.reset);
 } PRINT1(d,i.1)
 workover(i.1);
 workover(5)
 {
 (int i=5;
 i.workover = 0 * whatever;
 PRINT1(d,i.workover);
 return(i.workover);
 } PRINT1(d,i.1);
```
return(j.last=i.last--);

i.last = 9 but 10 is returned since the decrement occurs after the value is taken.

j.last dies with the return, but i.last lives on. Thus, when last is called again, i.last will be 9.

for(j.l=1; j.l<3; j.l++) {
    PRINT2(d,i.l,j.l);  
    PRINT1(d,new(i.l+j.l));
}

The effect of executing the loop body is to increment j.l by one. The loop has no effect on the value of i.l.

next ignores the value it is passed and returns the current value of i.o. As a side effect of executing next, i.o is incremented by one.

last also ignores the value of its passed argument. It returns the current value of its local static variable, i.last. As a side effect of executing last, i.last is decremented by one.

new returns the value of its argument plus 10. There are no lasting side effects.

Storage Classes 4.1

int i=1;
main()
{
    auto int i, j;
i.l = reset();
    extern int i;
    i.o = 1.
    next()
    {
        return(i.o);
        i.o is the external i referenced in reset.
i.o = 1.
    }

    The second source file begins with an external definition of a variable named i. This definition might appear to be in conflict with the external variable i defined in the first file. The designation static, however, tells the compiler that this i is known only within the current file. In other words, it is only known within the functions next, last, and new. We will reference it by i.lnn; i.lnn = 10.

    next()
    {
        return(i.lnn+1);
        i.lnn = 11 and next returns 11.
    }

    The declaration of next does not include any arguments. The value passed by main is ignored.

    last()
    {
        return(i.lnn-1);
        i.lnn = 10 and last returns 10. last references the same i previously incremented by next.
\begin{verbatim}
PRINT1(d,new(i+1+j));
new(2)
{{(int i=2;)
static int j=5;
return(i.new=j.new=5+2);
}
for(j=1; j<3; j++)
{ j=2.
In this iteration we will generalize about the  
effect of each statement.
PRINT2(d,i,j);
The effect of the loop is to increment j by one.
PRINT1(d,next(i));
next increments i.next and returns the  
resulting value.
PRINT1(d,last(i));
last decrements i.next and returns the  
resulting value.
PRINT1(d,new(i+1+j));
new adds its argument to j.new and returns  
the resulting sum.
}
}

Pointers and Arrays 1.1

int a[] = {0,1,2,3,4};
a is defined to be an array of five integers, with  
elements a[i]=i for i from 0 to 4.
for(i=0; i<4; i++)
PR(d,a[i]);
i takes on the values 0 to 4.
a[i] successively accesses each element of a.

Pointers and Arrays 1.2

int *p;

Declarations of the form type *x tell the compiler  
that when *x appears in an expression it yields a  
value of type type. *x is a pointer-to-type taking on  
values that are addresses of elements of type type.  
Type is the base type of x. In this problem, p is  
declared as a pointer-to-integer; the base type of p  
is int.
for(p=&a[0];
p<=&a[4];
PR(d,*p);
*p evaluates to the integer stored at the address  
contained in p. Since p holds &a[0], *p is  
a[0].
p++ )

When applied to a pointer variable, the increment  
operator advances the pointer to the next element  
of its base type. What actually happens is that the  
pointer is incremented by sizeof(base type)  
bytes. C does not test to insure that the resulting  
address is really that of a valid element of the base  
type. In this problem, p is advanced to the next  
element of a.
p<=&a[4]
p is again tested against the end of the array. The  
loop is terminated when p points beyond the last  
element of a. While in the loop, p points  
successively to each element of a in index order.
\end{verbatim}
Pointers and Arrays 1.3

```c
for ( p=&a[0], i=1; i<5; i++ )
    p points to the start of the array a. i takes on the values 1 through 5.
    PR(d,p[i]);
```

- `p` points to the start of the array `a`. `i` takes on the values 1 through 5.

**About arrays and indices.** Though by far the most common use of `[ ]` is to represent array subscripting, `[ ]` actually is a general indexing operator. `x[i]` is defined to be `*(x+i)`, where `x` is usually an address and `i` is usually integral. The rules of address arithmetic apply, so `i` is in units of `sizeof(base type of x)`.) (It should by now be clear why array indices begin at 0. An array name is actually a pointer to the first element in the array. An index is the offset from the array start. The offset to the first element from the array start is 0.) In this last problem, `i` is used to index off `p`. `p[i] = *(p+i) = *(a+i) = a[i]`. `i` goes from 1 to 5. When `i=5`, `p+i` points just beyond the end of the array, hence the value at `p+i` is unknown. This is such a common mistake, it is worth noting again: an array with `n` elements has indices of 0 through `n-1`.

Pointers and Arrays 1.4

```c
for( p=a+4; i=0; i<4; i++ )
    p gets the address of the first element of `a`.
    p=a, i=0, so p+i=a+0, which is less than a+4.
    PR(d,*(p+i));
    p points to the second element of `a`, `i` is 1.
    p=a+1, i=1, thus p+i=a+2.
    PR(d,*(p+i));
    p gets the address of the last element of `a`.
    p=a+4, i=0, so p+i=a+0, which is less than a+4.
    *(p+i) = *(a+i) = a[0].
    *(p+i) = *(a+0) = a[0].
    p points to the second element of `a`, `i` is 1.
    p=a+1, i=1, thus p+i=a+2.
    *(p+i) = a[2].
    p=a+2, i=2.
    p+i <= a+4
    PR(d,*(p+i));
    p++ , i++
    p+i <= a+4
    PR(d,*(p+i));
    p++ , i++
    p+i <= a+4
```

- `p` points to the start of the array `a`. `i` takes on the values 1 through 4.
- `p+i` successively refers to the elements of `a`. `p[i]` points outside of the array.
- `*(p+i)` is the value at that point.
- `p` is decremented to the preceding element.

**Pointers and Arrays 1.5**

```c
for( p=a+4; p>=a; p-- )
    p points to the fifth element of `a`.
    The loop terminates when `p` points below `a`.
    The integer pointed to by `p` is printed.
    p is decremented to the preceding element.
```

**Pointers and Arrays 1.6**

```c
for( p=a+4, i=0; i<=4; i++ )
    p points to the last element of `a`, `i` goes from 0 to 4.
    PR(d,p[-i]);
```

- `p` points to the start of the array `a`.
- `p+i` points to the element `i` away from the last element of `a`.
- `p[-i]` points to the element `i` away from the last element of `a`.

**Pointers and Arrays 1.7**

```c
for( p=a+4; p>=a; p-- )
    p points successively to the elements of `a` from the last to the first.
    PR(d,a[p-a]);
```

- `p` points to the start of the array `a`.
- `p` is decremented to the preceding element.
- `p` evaluates to the offset from the start of the array to the element pointed to by `p`.
- `p-a` is the index of the element pointed to by `p`.

**Pointers and Arrays 1.8**

```c
```

- `p` points to the start of the array `a`.
- `p` is decremented to the preceding element.
- `p` evaluates to the offset from the start of the array to the element pointed to by `p`.
Pointers and Arrays 2.1

```c
int a[] = {0,1,2,3,4};
int *p[] = {a,a+1,a+2,a+3,a+4};
int **pp = p;
```

- `a` is initialized to be an array of five integers.
- `*p[]` evaluates to an integer, thus `p[]` must point to an integer, and `p` is an array of pointer-to-integer. The five elements of `p` initially point to the five elements of `a`.
- `**pp` evaluates to an integer, hence `*pp` must point to an integer, and `pp` must point to a pointer-to-integer. `pp` initially points to `p[0]`.

Figure 2.1 illustrates the relationships between `pp`, `p`, and `a`.

```
pp
     
 p   0 1 2 3 4
 a
Figure 2.1
```

Pointers and Arrays 2.2

```
PRINT2(d,a,*a);
PRINT3(d,p,*p,**p);
PRINT3(d,pp,*pp,**pp);
```

- `print2(d,a,*a)`;
- `print3(d,p,*p,**p)`;
- `print3(d,pp,*pp,**pp)`;

As noted earlier, the name of an array is synonymous with the address of the first element in the array. The value of `a` is thus the address of the array `a`, and `*a` is equivalent to `a[0]`.

```
pp++
```

- `pp++` is a pointer to pointer-to-integer (the base type of `pp` is pointer-to-integer), so `pp++` increments `pp` to point to the next pointer in memory. The effect of `pp++` is indicated by the bold arrow in Figure 2.3-1.

```
pp-p
```

```
*pp-a
```

- `*pp-a` points to `p[1]` and `*pp` points to the second element of the array `a`. The value of `*pp` is thus `a[1]`.

```
**(pp++)
```

- `**(pp++)` is an increment, then an indirection. The bold arrow in Figure 2.3-2 shows the effect of the increment.

```
++++pp
```

- `++++pp` (Figure 2.3-3)

```
++++pp
```

- `++++pp` (Figure 2.3-4)
Pointers and Arrays 2.4

Figure 2.3-1

Figure 2.3-2

Figure 2.3-3

Figure 2.3-4

Figure 2.4-1 pp=p

Figure 2.4-2 *(pp++)

Figure 2.4-3 *(++(*pp))

Figure 2.4-4 ++(*pp)
Pointers and Arrays 3.1

```c
int a[3][3] = {
    {1, 2, 3},
    {4, 5, 6},
    {7, 8, 9}
};

int *pa[3] = {
    a[0], a[1], a[2]
};

int *p = a[0];
```

*a is a 3 by 3 matrix with rows 123, 456, and 789. a[i][j] evaluates to an integer at offset j from the start of row i. a[i] yields the address of the first element of row i. And a yields the address of the first row of the matrix a. Thus a is a pointer to three-element-integer-array, and a[] is a pointer-to-integer.

*p[a[]] evaluates to an integer, thus pa[] is a pointer-to-integer and pa is an array of pointer-to-integer. pa[0] is initialized to the first element of the first row of a, pa[1] to the first element in the second row, and pa[2] to the first element in the third row.

*p is a pointer-to-integer initially pointing to the first element of the first row of the matrix a.

Figure 3.1 illustrates the relationships between a, pa, and p.

Pointers and Arrays 3.2

```c
for(i=0; i<3; i++)
    a[i][2-i]
*a[i]
*(a+i)+1
```

i goes from 0 to 2 in the loop.

*a[] selects the diagonal from a[0][2] to a[2][0].
*a[] yields the address of the first element of the ith row in the matrix a. *a[] yields the value of the first element of the ith row.
*(a+i)+1 yields the address of the first element from the ith row.
*(a+i)+1 yields the address from the ith element from the ith row. And *(a+i)+1 gets the integer value from the ith element of the ith row.

Pointers and Arrays 3.3

```c
for(i=0; i<3; i++)
    pa[i]
*p[i]
```

i goes from 0 to 2 in the loop.

pa[] accesses the ith element of pa. *pa[] accesses the integer pointed to by the ith element of pa.
*p[i] points to the first element of the first row in the matrix a. Since the base type of p is int, p[i] yields the ith element of the first row in a.

About array addresses. We have noted several times that the address of an array and the address of the first element in the array have the same value. In this past puzzle, we saw that a and a[0] evaluated to the same address. One difference between the address of an array and the address of the first element in the array is the type of the address and, hence, the unit of arithmetic on an expression containing the address. Thus, since the type of a is pointer to three-element-integer-array, the base type of a is three-element-integer-array and a+1 refers to the next three-element-integer-array in memory. Since the type of a[0] is pointer-to-integer, the base type of a[0] is integer and a[0]+1 refers to the next integer in memory.
**Pointers and Arrays 4.1**

```c
char *c[] = {
  "ENTER",
  "NEW",
  "POINT",
  "FIRST"
};
```

*c[]* evaluates to a character, so *c[]* points to characters and *c* is an array of pointer-to-character. The elements of *c* have been initialized to point to the character arrays "ENTER", "NEW", "POINT", and "FIRST".

```c
char **cp[] = {
  c+3, c+2, c+1, c
};
```

**cp[]** evaluates to a character, **cp[]** is a pointer-to-character, and *cp[]* is a pointer-to-pointer-to-character. Thus *cp* is an array of pointers to pointer-to-character. The elements of *cp* have been initialized to point to the elements of *c*.

```c
char ***cpp = cp;
```

***cpp*** evaluates to a character, ***cpp*** points to a character, **cpp*** points to a pointer-to-character, and *cpp*** points to a pointer-to-pointer-to-character.

Figure 4.1 illustrates the relationships between **cpp**, *cp*, and *c*.

---

**Pointers and Arrays 4.2**

```c
(*(*(*(++cpp)))
```

Increment *cpp* then follow the pointers.

(Figure 4.2-1)

```c
(*(*(-(*(*(++cpp)))))) + 3
```

Increment *cpp*, follow the pointer to *cp[2]*, decrement *cp[2]*, follow the pointer to *c[0]*, index 3 from the address in *c[0]*. (Figure 4.2-2)

```c
(*(*cpp[(-2)])) + 3
```

Indirectly reference -2 from *cpp* yielding *cp[0]*, follow the pointer to *c[3]*, index 3 from the address in *c[3]*. (Figure 4.2-3)

```c
((cpp[-1])[-1]) + 1
```

Indirectly reference -1 from *cpp* yielding *cp[1]*, indirectly reference -1 from *cp[1]* yielding *c[1]*, index 1 from the address in *c[1]*. (Figure 4.2-4)

---

**About pointers.** If you can work this puzzle correctly then you know everything you will ever need to about the mechanics of using pointers. The power of pointers lies in their generality: we can chain them together to form an endless variety of complex data structures. The danger of pointers lies in their power: complex pointer chains are seldom readable and even more seldom reliable.
Structures 1.1

The structure tag S1 refers to a structure containing a character array, c, of length 4, and a character pointer, s. The structure variable s1 is an instance of the structure S1 initialized to

```cpp
static struct S1 {
    char c[4], *s;
} s1 = { "abc", "def" };
```

The structure has been defined as static so that it may be initialized in the definition.

The structure tag S2 refers to a structure containing a character pointer, cp, and an instance of the structure S1, ss1. The structure variable s2 is an instance of the structure S2 initialized to

```cpp
static struct S2 {
    char *cp;
    struct S1 ss1;
} s2 = { "ghi", { "jkl", "mno" } };
```

Figure 1.1 depicts the structures s1 and s2.
Structures 1.2

PRINT2(c, (s1.c)[0])
A character is to be printed.
Reference the first character of the c field of the structure s1.
(Figure 1.2-1)

*(s1.s)
Reference the character pointed to by the s field of the structure s1.
(Figure 1.2-2)

Figure 1.2-1

Figure 1.2-2

Structures 1.3

PRINT2(s, s1.c)
A string is printed.
Reference the string pointed to by the c field of the structure s1. Recall that c = &c[0].
(Figure 1.3-1)

s1.s
Reference the string pointed to by the s field of the structure s1.
(Figure 1.3-2)

Figure 1.3-1

Figure 1.3-2
Structures 1.4

```
struct S1 {
    char *s;
    int i;
    struct S1 *s1p;
};
```

Figure 1.4-1 s2.cp

```
static struct S1 a[] = {
    {"abcd", 1, a+1.},
    {"efgh", 2, a+2 },
    {"ijkl", 3, a }
};
```

Figure 1.4-2 (s2.ss1).s

Structures 1.5

```
struct S1 *p=a;
```

Figure 1.5-1 ++(s2.cp)

```
p a[0] s a[1] s a[2] s
  i 1 2 3
  s1p

Figure 2.1
```

Structures 2.1

```
S1 is declared to be a tag referring to a structure containing a character pointer, s, an integer, i, and a pointer to structure of type S1, s1p. This is only a declaration; an instance of S1 is not created.
```

```
a is a three-element array with elements of type structure S1. a has been defined as static so that it can be initialized in the definition.
```

```
p is a pointer to structures of type S1. p is initialized to point to the first element of a.
```

Figure 2.1 depicts the array a and the pointer p.
Strings are to be printed.

Reference the string pointed to by the s field of the structure that is the first element of a. (Figure 2.2-1)

Reference the string pointed to by the s field of the structure pointed to by p. (Figure 2.2-2)

Reference the string pointed to by the s field of the structure pointed to by the s1p field of the structure that is the third element of a. (Figure 2.2-3)
for (i=0; i<2; i++) {
    PR(d, --((a[i]).i))
}

PR(c, ++(((a[i]).s)[3]))

i takes on the values of 0 and 1.
Print an integer.
Decrement then reference the integer in the i field of the structure that is the i'th element of a. (Figure 2.3-1 shows the case for i=0)
Print a character.
Increment then reference the fourth character of the string pointed to by the s field of the structure that is the i'th element of a. (Figure 2.3-2 shows the case for i=0)
Structures 2.4

\[ ++(p->s) \]

Increment the \( s \) field of the structure pointed to by \( p \), then output the string pointed to by the \( s \) field. (Figure 2.4-1)

\[ a[((++p)->i)].s \]

First \( p \) is incremented, then the \( s \) field of the \( p->1 \)th structure of \( a \) is accessed. (Figure 2.4-2)

\[ a[(-(p->s1p)->i)].s \]

The \( i \) field of the structure pointed to by the \( s1p \) field of the structure pointed to by \( p \) is decremented then used as an index into \( a \). (Figure 2.4-3)
Structures 3.1

```c
struct S1 {
    char *s;
    struct S1 *s1p;
};

static struct S1 a[] = {
    {"abcd", a+1 },
    {"efgh", a+2 },
    {"ijkl", a }
};

struct S1 *(p[3]);
```

S1 is declared to be a tag referring to a structure containing a character pointer, s, and a pointer to structure of type S1, s1p.

a is a three-element array with elements of type structure S1. a has been defined as static so that it can be initialized in the definition.

When encountered in a program statement, the expression *(p[]) yields a structure S1. Thus, p[i] points to a structure S1, and p is a three-element array of pointers to structures of type S1.

Figure 3.1 depicts the arrays a and p.

```
for (i=0; i<3; i++)
p[i] = (a[i]).s1p;
```

i takes on the values 0, 1, 2.

The 0th element of p gets a copy of the pointer in the s1p field of the 0th element of a. (Figure 3.2-1)

These are all ways of saying the same thing. (Figure 3.2-2)
**Structures 3.3**

```c
swap(*p, a);

temp = (&a[1])->s;
(a[1])->s = (&a[0])->s
(&a[0])->s = temp
(p[0])->s, (*p)->s
(**p)->s1p)->s
```

- `p` points to `p[0]`, so `*p` yields the content of `p[0]` or `&a[1]`. `a` yields `&a[0]`.
- Equivalently, `temp = a[1].s`.
- Or, `a[1].s = a[0].s`
- `swap` swaps the strings pointed to by the `s` fields of its arguments. (Figure 3.3-1)

(Figure 3.3-2)

(Figure 3.3-3)

**Figure 3.3-1**

**Figure 3.3-2**

Figure 3.4-4 `++(*(++(*(p)->s1p))).s)`
To understand the effect of a preprocessor macro, expand it in place.

Always expand the leftmost macro.
First, substitute the macro replacement string for the macro call.

Then substitute the argument(s) in the call for those in the replacement string.
Expand the leftmost macro, PR, this time.

A macro name that occurs between quotes is not expanded. However, macro arguments are expanded wherever they occur in the macro body. Thus, \texttt{x*FUDGE(2)} replaces \texttt{a} in the macro \texttt{PR}, but \texttt{FUDGE(2)} is left unexpanded in the format of the call to \texttt{printf}.

Beware! Macros can be a source of subtle trickery. Expanding a macro is strictly a matter of replacing one string by another. The macro preprocessor knows next to nothing about C. Most surprises can be avoided by adhering to a few conventions.

Convention 1: Parenthesize all macro bodies that contain operators.

The unwanted interaction between the replacement string and its context in this problem is avoided if \texttt{FUDGE(k)} is defined to be \texttt{(k+3.14159)}.

The call to \texttt{PRINT2} may look like a single statement, but it expands to three. Only the first \texttt{PR} is contained within the for loop. The second \texttt{PR} is executed following the loop, with \texttt{cel=150}.

Convention 2: Keep macro bodies cohesive; prefer an expression to a statement, a single statement to multiple statements.

For this problem, using commas in place of the semicolons in the body of the \texttt{PRINT} macros satisfies Convention 2.
160 THE PREPRO (SOR DOESN'T KNOW C

Preprocessor 1.3

```
int x=1, y=2;
PRINT3( MAX(x++,y), x, y);
(a<b ? b : a), x, y
```

The PRINT3 macro is, of course, expanded before MAX. However, to avoid obscuring
the point of the puzzles, in this and following solutions the PRINT macros will
not be expanded. The first step then is to substitute the replacement string for the call
to MAX.

```
(x++<y ? y : x++), x, y
```

Next, substitute the actual arguments for
the formal arguments.

```
2
``` Finally, evaluate.

```
PRINT3( MAX(x++,y), x, y );
```

Now execute the second call to PRINT3.

```
(x++<y ? y : x++), x, y
(2<2 ? y : x++), and x=2
(y)
2
```

PRINT3( MAX(x++,y), x, y );
(x++<y ? y : x++), x, y
(2<2 ? y : x++), and x=3
(x++)
3, and x=4

```
++ appears only once in the macro call but twice in the expansion, causing x to be
incremented sometimes by one and sometimes by two. The burden of protecting against
such unfortunate side effects can be placed either with the macro writer or the macro user.

Convention 3: Avoid macro bodies that can cause obscure or inconsistent side effects.
Convention 3A: Avoid expressions with side effects in macro calls.

In general, the problem of side effects in macros is quite tricky. Following Convention 3
often means copying arguments into local variables within the macro; this extra overhead
reduces the speed advantage of macro calls over function calls. Following Convention 3A
requires knowing when a routine has been coded as a macro rather than a function; at best,
this violates the notion of the routine as an abstraction, and at worst, the routine may be
rewritten causing the assumption no longer to be valid.

For this problem following Convention 3A preserves MAX intact.

Preprocessor 2.1

```
int x=1;
PRINT( -NEG(x) );
---a
```

First substitute the macro replacement string for the macro call. (As before, the PRINT
macro will not be expanded.)

```
---x, and x=0
```

Then substitute the argument in the call for the
one in the replacement string.

The macro replacement string is exactly those characters that follow the closing parenthesis
of the argument list. The trick in this puzzle is that the --a immediately
follows the parenthesis. Still, following Convention 1 by defining NEG(a) to be (--a) produces the
expected expansion. It is also a good practice to begin each replacement string with either a
tab or a space.

Preprocessor 2.2

```
PRINT( weeks(10080) )
(days(10080)/7)
```

Replace each macro call with the macro body.
Notice that there is not a conflict between the macro parameter mins and the macro mins.

```
(hours(10080)/24)/7
(((10080/60)/24)/7)
1
```

Evaluate.

```
PRINT( days(mins(86400) )
(hours(mins(86400))/24)
(((mins(86400)/60)/24)
1
```

Expand the leftmost macro.

```
Evaluate.
```
Preprocessor 2.3

static char input = "\twhich\if?";
if(c<' ') TAB(c,i,oldi,temp);
else putchar(c);

if(c<' ')
    if(c=='	')
        for(temp=i-(oldi-1)%8,oldi=i; temp; temp--)
            putchar(' ');
    else putchar(c);

TAB includes an open if statement. On expansion, the if consumes the following else.

Convention 4: Make macro replacement strings complete C entities, be they expressions, statements (minus the closing semicolon), or blocks.

For this problem, appending a null else clause to the TAB macro alleviates the difficulty. (Notice that enclosing the macro replacement string in braces, i.e., making it a block, does not solve the problem.)

About macros and functions. Very often a routine can be implemented using either a macro or a function. The advantage of using a macro is that it will be executed faster since the runtime overhead of a function call is avoided. The advantages of using a function are that none of the tricky situations we've seen in the puzzles with macros will occur, and if the routine is called several times, the implementation will probably require less memory. This leads us to the final convention for using macros:

Convention 5: Keep macros simple. If you can't keep a macro simple, make it a function.
APPENDIX 1: Precedence Table

<table>
<thead>
<tr>
<th>OPERATOR</th>
<th>ASSOCIATIVITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>primary: ( [ ] -&gt; .</td>
<td>left to right</td>
</tr>
<tr>
<td>unary: 1 + - + - (type) * &amp; sizeof</td>
<td>right to left</td>
</tr>
<tr>
<td>multiplicative: * / %</td>
<td>left to right</td>
</tr>
<tr>
<td>additive: + -</td>
<td>left to right</td>
</tr>
<tr>
<td>shift: &lt;&lt; &gt;&gt;</td>
<td>left to right</td>
</tr>
<tr>
<td>relational: &lt; &lt;= &gt; &gt;=</td>
<td>left to right</td>
</tr>
<tr>
<td>equality: == !=</td>
<td>left to right</td>
</tr>
<tr>
<td>bitwise: &amp;</td>
<td>left to right</td>
</tr>
<tr>
<td>bitwise: ^</td>
<td>left to right</td>
</tr>
<tr>
<td>bitwise:</td>
<td>left to right</td>
</tr>
<tr>
<td>logical: &amp;&amp;</td>
<td>left to right</td>
</tr>
<tr>
<td>logical:</td>
<td></td>
</tr>
<tr>

<td>right to left</td>
</tr>
<tr>
<td>assignment: += -= etc.</td>
<td>right to left</td>
</tr>
<tr>
<td>comma: ,</td>
<td>left to right</td>
</tr>
</tbody>
</table>

The precedence table illustrates the relative precedence of operators. Precedence determines the order in which operands are bound to operators. Operators receive their operands in order of decreasing operator precedence.

To determine the relative precedence of two operators in an expression find the operators in the OPERATOR column of the table. The operator higher in the list has the higher precedence. If the two operators are on the same line in the list, then look at the corresponding ASSOCIATIVITY entry. If it indicates "left to right", then the operator to the left in the expression has the higher precedence; if it indicates "right to left", then vice versa.
### APPENDIX 2: Operator Summary Table

**Arithmetic operators** (operands are numbers and pointers)

- **Additive**
  
<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x+y</code></td>
<td>sum of <code>x</code> and <code>y</code></td>
<td>if either operand is a pointer the other must be integral†</td>
</tr>
<tr>
<td><code>x-y</code></td>
<td>difference of <code>x</code> less <code>y</code></td>
<td>if either operand is a pointer the other must be integral or a pointer of the same base type</td>
</tr>
</tbody>
</table>

- **Multiplicative**
  
<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x*y</code></td>
<td>product of <code>x</code> and <code>y</code></td>
<td><code>x</code>, <code>y</code> must not be pointer</td>
</tr>
<tr>
<td><code>x/y</code></td>
<td>quotient of <code>x</code> divided by <code>y</code></td>
<td><code>x</code>, <code>y</code> must not be pointer</td>
</tr>
<tr>
<td><code>x^y</code></td>
<td>remainder of dividing <code>x</code> by <code>y</code></td>
<td><code>x</code>, <code>y</code> must not be double, float, or pointer</td>
</tr>
<tr>
<td><code>-x</code></td>
<td>arithmetic negation of <code>x</code></td>
<td><code>x</code>, <code>y</code> must not be pointer</td>
</tr>
</tbody>
</table>

- **Incremental**
  
<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x++</code> (x--)</td>
<td><code>x</code></td>
<td><code>x</code> must be a reference to a numeric value or a pointer</td>
</tr>
<tr>
<td></td>
<td><code>x</code> is incremented (decremented) after use</td>
<td></td>
</tr>
<tr>
<td><code>++x</code> (x--)</td>
<td><code>x+1</code> (x-1)</td>
<td><code>x</code> must be a reference to a numeric value or a pointer</td>
</tr>
<tr>
<td></td>
<td><code>x</code> is incremented (decremented) before use</td>
<td></td>
</tr>
</tbody>
</table>

† Integral stands for the types int, char, short, long, and unsigned.
### Assignment operators

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x=y</code></td>
<td><code>y</code> cast in the type of <code>x</code>, <code>x</code> gets the value of <code>y</code></td>
<td><code>x, y</code> may be any type but array</td>
</tr>
<tr>
<td><code>x op= y</code></td>
<td><code>x op (y)</code> cast in the type of <code>x</code>, <code>x</code> gets the value of <code>x op (y)</code></td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
</tbody>
</table>

### Bitwise operators (operands are integral)

#### Logical

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x&amp;y</code></td>
<td>bit by bit AND of <code>x</code> and <code>y</code>; AND yields a 1 for each place both <code>x</code> and <code>y</code> have a 1, 0 otherwise</td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
<tr>
<td>`x</td>
<td>y`</td>
<td>bit by bit inclusive OR of <code>x</code> and <code>y</code>; inclusive OR yields a 0 for each place both <code>x</code> and <code>y</code> have a 0, 1 otherwise</td>
</tr>
<tr>
<td><code>x^y</code></td>
<td>bit by bit exclusive OR of <code>x</code> and <code>y</code>; exclusive OR yields a 0 for each place <code>x</code> and <code>y</code> have the same value, 1 otherwise</td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
<tr>
<td><code>-x</code></td>
<td>one's-complement of <code>x</code>; 1s become Os and Os 1s</td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
</tbody>
</table>

#### Shift

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x&lt;&lt;y</code></td>
<td><code>x</code> left shifted <code>y</code> places, the lowest <code>y</code> bits get Os</td>
<td><code>y</code> must be positive and less than the number of bits per computer word</td>
</tr>
<tr>
<td><code>x&gt;&gt;y</code></td>
<td><code>x</code> right shifted <code>y</code> places; the highest <code>y</code> bits get Os for positive <code>x</code>, 1s or Os depending on the</td>
<td><code>y</code> must be positive and less than the number of bits per computer word</td>
</tr>
</tbody>
</table>

### Logical operators (operands are numbers and pointers)

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x&amp;&amp;y</code></td>
<td>AND of <code>x</code> and <code>y</code>; result is of type int</td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
<tr>
<td>`x</td>
<td></td>
<td>y`</td>
</tr>
<tr>
<td><code>!x</code></td>
<td>logical negation of <code>x</code>; result is of type int</td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
</tbody>
</table>

### Comparison (operands are numbers and pointers)

#### Relational

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x&lt;y</code></td>
<td>1 if <code>x</code> is less than (<code>greater than</code>) <code>y</code>, 0 otherwise</td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
<tr>
<td><code>x&lt;=y</code></td>
<td>1 if <code>x</code> is less than or equal to (<code>greater than</code> or equal to) <code>y</code>, 0 otherwise</td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
</tbody>
</table>

#### Equality

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x==y</code></td>
<td>1 if <code>x</code> is equal to (<code>not equal to</code>) <code>y</code>, 0 otherwise</td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
</tbody>
</table>

#### Conditional

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x?y:z</code></td>
<td><code>y</code> if <code>x</code> is nonzero, <code>z</code> otherwise</td>
<td><code>x, y</code> may be any type but array or structure</td>
</tr>
</tbody>
</table>
### OPERATOR SUMMARY TABLE

#### Address operators

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>*x</td>
<td>the value at the address contained in x cast in the base type of x</td>
<td>x must be a pointer</td>
</tr>
<tr>
<td>&amp;x</td>
<td>the address of x</td>
<td>x must be a reference to a value</td>
</tr>
<tr>
<td>x[y]</td>
<td>the value at the address x+y cast in the base type of the address operand</td>
<td>one of the operands must be an address and the other must be integral</td>
</tr>
<tr>
<td>x.y</td>
<td>the value of the y field of the structure x</td>
<td>x must be a structure, y a structure field</td>
</tr>
<tr>
<td>x-&gt;y</td>
<td>the value of the y field of the structure at the address x</td>
<td>x must be pointer to a structure, y a structure field</td>
</tr>
</tbody>
</table>

#### Type operators

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>(type)x</td>
<td>x cast in the type type</td>
<td>x may be any expression</td>
</tr>
<tr>
<td>sizeof(x)</td>
<td>the size in bytes of x</td>
<td>x may be any expression</td>
</tr>
<tr>
<td>sizeof(type)</td>
<td>the size in bytes of an object of type type</td>
<td></td>
</tr>
</tbody>
</table>

#### Sequence operator

<table>
<thead>
<tr>
<th>operator</th>
<th>yields</th>
<th>restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>x,y</td>
<td>y is evaluated before y</td>
<td>x, y may be any expression</td>
</tr>
</tbody>
</table>
The type hierarchy chart illustrates the ordering of the arithmetic types. The execution of each arithmetic operator in an expression yields a result with the type of its highest typed operand. Similarly, when two quantities are compared by a relational operator, the lower typed operand is cast in the type of the higher typed operand. The vertical arrows in the chart show the basic ordering: double is the highest type, int the lowest. The horizontal arrows indicate the automatic type conversions. That is, operands of type float are always converted to type double before being considered in an expression. Likewise, operands of types char and short are always converted to type int.
